MOTIVATIONAL INTERVIEWING

The spirit of motivational interviewing (MI) is characterized by partnership, evocation, acceptance, and compassion and is an effective strategy for working with clients in treatment and assessment capacities. MI incorporates a collaborative partnership between the practitioner (therapist or assessor) and client. MI is effective for enhancing criminal justice assessments. For example, when used in risk assessment, MI has made the process collaborative rather than adversarial and helps the clinician obtain information in an efficient manner. Moving from risk identification and assessment to criminal justice treatment, MI has been used as a stand-alone intervention or part of a multicomponent treatment program. It has been delivered to

adolescents, teenagers, and adults, in-person individually or in groups—and has also branched to telephone and computer-based interventions.

MI is used in closed and open custody settings and in community supervision. Target behaviors have included alcohol and other drug use, driving while intoxicated, interpersonal violence, predatory aggression, and sexual offending. It has been effective in increasing problem recognition, importance of change, readiness to change, treatment uptake, and treatment compliance. Retention in treatment has been shown, with fewer dropouts relative to other interventions. Outcomes include improved treatment compliance, decreases in target behaviors, and decreased risk in subsequent substance use.

MI is also used with probation officers in evidence-based community supervision. Correctional officers and other prison personnel have been trained to use MI (e.g., in Scandinavia and North America). Correctional personnel trained to use MI have shown decreased stress reactions in a prison setting. Criminal justice personnel have diverse responsibilities including diversion, detention, treatment, and supervision of individuals involved with criminal justice. Behavior change in service of rehabilitation and ultimately decreased recidivism is a common goal across jurisdictions, but behavior change can be challenging and imperfect. This is especially true in closed custody settings, community residential facilities, and other settings where inmates and offenders are found. MI is based in sound psychological theory, supported by an empirical evidence base, practiced widely, and a viable approach for use in criminal justice. This entry focuses on the use of MI for behavior change.

The Four Processes of MI

Four processes integral to MI are *engaging*, *focusing*, *evoking*, and *planning*. Engaging develops rapport between practitioner and client. Trust and respect help develop a strong working alliance. Focusing is having clear, mutually agreed-upon goals and a shared direction in the conversation about change. Evoking is strategically eliciting and strengthening the individual's internal motivation for change. Often, this occurs when assisting the individual in resolving ambivalence about change. The goal is to increase the individual's

perceived advantages of change relative to the perceived disadvantages of change. Evoking, and the directive nature of its differential reinforcement of the client's change talk, is unique and central to practicing MI. Planning is strengthening the client's commitment to behavior change and developing an action plan that supports the client's change efforts.

Core Counseling Skills

Four counseling skills essential to the spirit of MI are asking *open questions*, *affirming*, *reflective listening*, and *summarizing*, often referred to as OARS. Open questions help gather information and encourage discussion. Reinforcing individual strengths and positive intentions and steps by using affirmations provides encouragement and support. A fundamental skill of MI is reflective listening. The practitioner uses it to express empathy. Reflective listening is used selectively to choose specific material to reflect. Practitioner use of reflection permits the individual to hear (again) thoughts and feelings that he or she expressed. Reflective listening statements range from simple to complex. Complex reflections add meaning and emphasis and address unspoken content including emotions and nonverbal behavior. They move the conversation forward, in the direction of change, by encouraging the individual to talk, consider, and explore. Summarizing permits the practitioner to gather information that the individual has said and reflect it back to the individual for consideration. Used skillfully, these techniques contribute to MI being person centered, tailored to the individual's needs. Theories addressing self-regulation, self-perception, self-efficacy, and self-determination contribute to understanding behavior change and the practice of MI.

Change Talk

Change talk is client speech expressed as an argument for behavior change. Practitioners use the therapeutic techniques described earlier to selectively elicit and reinforce change talk. Change talk comprises preparatory and mobilizing subtypes. Preparatory change talk reflects the individual's desire, ability, reasons, and need related to the perceived advantages of change. Techniques for

evoking preparatory change talk include asking open questions, using importance and confidence rulers, querying extremes (e.g., exploring the worst outcome if the status quo is maintained and the best outcome if change is successful), looking back and developing discrepancy between the individual's life before the problem existed and his or her current life, exploring goals and values, and developing discrepancy between the individual's current behavior and his or her goals and values.

Mobilizing change talk illustrates the resolution of ambivalence in favor of change. It reflects commitment (e.g., promises/contracts), activation (e.g., movement toward taking action), and taking steps (e.g., completing an action consistent with change). The practitioner responds to change talk by asking for elaboration, affirming, reflecting, and summarizing.

While change talk is the client's speech favoring behavior change, the client's speech can also reflect maintenance of the status quo (i.e., arguments against change). The latter is sustain talk. MI practitioners respond to sustain talk with specific types of reflective listening statements, by emphasizing autonomy and by reframing the issue so the individual can consider a different perspective that could be conducive to behavior change.

MULTIDIMENSIONAL TREATMENT FOSTER CARE

See Treatment Foster Care Oregon

MULTISYSTEMIC THERAPY

Multisystemic therapy (MST) is a family-based treatment that was originally developed to address serious and violent juvenile offending and that has since been adapted to the treatment of other complex clinical problems in youths. MST interventions target risk factors at multiple levels of youths' social ecologies (i.e., individual, family, school, peer, neighborhood) and are delivered in the natural contexts in which problems occur (e.g., home and other community settings). This entry provides an overview of the theoretical, empirical, and clinical foundations of the MST model; describes three adaptations of the model: MST for Problem Sexual Behavior (MST-PSB), MST for Child Abuse and Neglect (MST-CAN), and MST-Psychiatric; and provides information about ongoing efforts to disseminate MST and its adaptations into community settings.

Theoretical and Empirical Foundations

The MST model is based on family systems theory and the theory of social ecology. Family systems theory posits that youth behavior problems are developed and maintained in part by problematic interactions between family members. Therefore, family systems therapists first examine the *fit* between problem behaviors and family relations and then target the family system in interventions. This theory also emphasizes the reciprocal nature of problematic behavior cycles within the family system; for example, a therapist working from a systemic conceptual framework would consider not only how parenting strategies affect a youth's disruptive behavior but also how the behavior of the youth shapes and guides the behavior of the parents as well as what function any misbehavior might serve in the family. The theory of social ecology further broadens the conceptualization of

youths' problem behaviors to include the influences of extrafamilial systems (i.e., peer, school, neighborhood, and broader community) in addition to the characteristics of the individual youth and his or her family members. This latter theory emphasizes the direct effects of familial and extrafamilial systems as well as the interactions between various systems on youth behaviors.

Consistent with these two theories, researchers have identified a number of correlates and causes of behavior problems at each level of the youth's social ecology. Variables associated with youth antisocial behavior are presented next as an illustration; additional risk factors are associated with other complex clinical problems targeted by adaptations of MST. At the individual youth level, antisocial behavior is associated with impulsivity, hostile attributional biases, lack of guilt for transgressions, and positive attitudes toward delinquency and substance use. At the family level, key risk factors include inconsistent and lax discipline, high conflict between family members, low caregiver warmth, and low levels of caregiver supervision. At the peer level, antisocial youths tend to associate with deviant peers and often experience high levels of rejection from prosocial peers. At the school level, youth criminality is related to poor school performance, behavior problems in school (e.g., truancy and suspension), negative attitudes toward school, and ineffective school responses to behavior problems (e.g., zero-tolerance policies). At the neighborhood level, youth antisocial behavior is associated with ease of access to weapons or drugs, exposure to neighborhood violence, and few sources of social support (e.g., prosocial neighbors, community institutions such as places of religious worship). Given the complex and multidetermined nature of youth antisocial behavior, MST is designed to target risk factors across the multiple systems in which youths are embedded.

The MST theory of change builds directly on family systems and social-ecological theories as well as on research findings regarding the determinants of youth antisocial behavior. More specifically, MST interventions focus on empowering caregivers to be more effective in monitoring, supervising, and supporting the youth, which then lead to improvements in other key systems (e.g., disengaging the youth from deviant peers,

enhancing the youth's performance in school) and, ultimately, to reductions in the youth's problematic behaviors. The ultimate aim is to surround the youth with a context that now supports prosocial behavior (e.g., prosocial peers, involved and effective caregivers, supportive school) rather than a context that is conducive to antisocial behavior. Thus, MST therapists address risk factors for youth problem behaviors at multiple levels of the social ecology but place particular emphasis on working with caregivers to develop skills that will maintain such changes (e.g., positive discipline practices, effective communication with school personnel).

The effectiveness of MST in the treatment of serious juvenile offenders is supported by more than a dozen clinical trials. Early studies conducted in the 1970s and 1980s established MST as a promising intervention by demonstrating posttreatment reductions in youth behavior problems, criminal activity, and association with deviant peers, as well as improvements in family functioning and youth peer relations. In addition, follow-ups conducted more than 20 years after treatment completion revealed that compared to a commonly used community outpatient treatment for juvenile offenders (i.e., individual therapy), MST produced lower rates of criminal recidivism and involvement in family-related civil suits among offenders as well as lasting economic benefits to taxpayers and crime victims. Furthermore, groups of independent investigators in the United States, the United Kingdom, Norway, and the Netherlands have conducted clinical trials that also support the effectiveness of MST.

Clinical Foundations

MST is delivered by dedicated treatment teams that consist of two to four therapists and a supervisor. MST therapists are generalists who provide an array of mental health services and coordinate access to additional services (e.g., medical, educational) that are necessary to address youth behavior problems and associated risk factors. Therapists typically have a master's degree in a mental health profession (e.g., psychology, social work) and carry caseloads of four to six families for an average of 3–5 months per case. MST interventions are delivered in community settings (e.g., family

home, school, recreation center) at times convenient to the family (e.g., night, weekends), with therapists available 24 hr a day, 7 days a week for crisis intervention. The intensity of services is varied to meet families' needs, often involving a high frequency of contact initially (e.g., 3–4 times per week) and gradually tapering off as youth and family functioning improves (as infrequently as once a week).

MST therapists vary the sequence and nature of interventions that are implemented based on the strengths and needs of a given family. Thus, rather than following a rigid protocol with sets of prearranged tasks, MST therapists use individualized interventions that are guided by nine overarching treatment principles (e.g., emphasizing the youth's and family's strengths as levers for change; promoting responsible behavior and decreasing irresponsible behavior by family members). Furthermore, intervention outcomes are evaluated continuously from multiple perspectives to identify advances in treatment as well as barriers to success that need to be addressed by future interventions.

Adaptations of MST

Based on the success of MST in treating serious and violent juvenile offenders, several groups of investigators have adapted the MST model to treat other complex clinical problems in youths. Three of these adaptations are currently being disseminated in community settings, including MST-PSB, MST-CAN, and MST-Psychiatric. Each adaptation is guided by the same principles and uses many of the same evidence-based techniques as in standard MST but focuses on aspects of a youth's ecology that are functionally related to the targeted problems.

MST-PSB

The MST-PSB approach has demonstrated positive long-term effects on youth behavior in three randomized clinical trials with juvenile sexual offenders. In general, MST-PSB interventions aim to reduce caregiver and youth denial about the sexual offense or offenses, remove barriers to effective parenting, enhance parenting knowledge, and promote affection and communication among

family members. In particular, the MST therapist works with caregivers and other appropriate persons (e.g., teachers) to develop plans for risk reduction and victim safety. In addition, interventions often target youth social skill and problem-solving deficits to promote the development of friendships with similar-aged, prosocial peers as well as age-appropriate sexual experiences. In some cases, individual interventions are used with the youth or caregiver to modify social perspective-taking skills, belief systems, or attitudes that contributed to the sexual offending.

MST-CAN

The MST-CAN model has shown considerable promise in two randomized clinical trials with youths who experienced physical abuse and their caregivers. Interventions typically begin with a functional analysis of abuse incidents to create a safety plan that outlines the steps family members would take to prevent future incidents of physical abuse. When appropriate, MST-CAN therapists consult with child psychiatrists who have been trained in the MST model to help families with medication management. In addition, the treatment team works closely with child protective service agencies to ensure that child protective service decision-making is based on clinical need and family progress. Moreover, a clarification process is used to help the caregiver who perpetuated the abuse to address cognitions about the abuse incident, accept responsibility for the abuse, and apologize to the child victim. In some instances, individual cognitive behavioral and behavioral interventions are also used with the caregiver and/or youth.

MST-Psychiatric

The MST-Psychiatric adaptation was designed as an alternative to hospitalization for youths with significant functional impairment due to psychiatric illness (e.g., severe mood disorders, suicidal or homicidal ideation, psychotic disorders) and has demonstrated positive effects on youth behavior in two randomized clinical trials. As in the MST-CAN model, MST-Psychiatric teams include child psychiatrists who have been trained in the MST model. Key differences from standard

MST include increased supervisory time for therapists, reduction of caseloads to three families per therapist, and the addition of two bachelor's-level crisis caseworkers to assist the team with clinical and administrative tasks.

Dissemination of MST

The developers of MST have established purveyor organizations to facilitate the transport of the standard MST model and its adaptations to community settings. These organizations license MST teams and provide ongoing quality assurance and training that are essential to maintaining fidelity to the MST model when delivered by provider agencies in the community. To date, there are over 500 MST teams (standard and adapted combined) in 34 U.S. states and in 16 countries, serving approximately 23,000 youths per year.

The dissemination procedures for standard MST and its adaptations ensure fidelity to the MST model in several ways. First, newly established teams participate in a comprehensive 5-day training on the MST model, with supplementary trainings required for teams that deliver adaptations of the model. Second, therapists and supervisors participate in ongoing (weekly) case consultations with an MST expert consultant. Third, these expert consultants provide quarterly 2-day booster training sessions for each team on site. Fourth, treatment adherence for therapists, supervisors, and consultants is continuously monitored through well-validated web-based measures. Given that adherence to the MST model (at all levels of the dissemination process) is associated with treatment effectiveness, MST teams that do not maintain high adherence are targeted for additional training.

Conclusions

Several decades of empirical work suggest that MST is effective in reducing complex clinical problems in youths, including serious and violent offending, sexual offending, child abuse and neglect, and serious psychiatric problems. The clinical effectiveness of MST has important implications that can help guide the continued development of psychosocial interventions for such challenging populations.

A key feature of MST pertains to its comprehensive and flexible nature, which includes an explicit focus on addressing key social-ecological risk factors (i.e., at the level of the individual youth, family, peers, school, and community). In contrast, a major limitation of usual community services for youths is their relatively narrow focus. Another important aspect of MST pertains to the accessibility and ecological validity of services. Specifically, MST is provided in the community contexts in which youth problem behaviors occur, which permits more accurate assessment of identified problems and of intervention results, diminishes barriers to service access, and promotes long-term maintenance of therapeutic changes. In contrast, traditional mental health services for youths (e.g., office-based therapy, residential treatment centers, hospitalization) often have little bearing on the environmental conditions that contributed to the youths' clinical problems. It seems likely that these features, combined with other aspects of MST (e.g., high levels of accountability for engaging families and achieving favorable clinical outcomes, extensive quality assurance protocols), produce the positive effects of MST on complex clinical problems in youths.

NATIONAL INSTITUTE OF JUSTICE

The National Institute of Justice (NIJ) is a research, development, and evaluation agency within the U.S. Department of Justice. It was established in 1986 through the authority of the Omnibus Crime Control and Safe Streets Act of 1986 as a way to provide evidence-based tools to criminal justice agencies and practitioners. The director of NIJ is appointed by the president of the United States to lead the agency.

The mission of NIJ is to advance knowledge and understanding of criminal justice issues through scientific methods. One of the aims of the NIJ is to provide impartial and objective knowledge and tools to better inform decision makers and criminal justice agents with regard to addressing crime reduction justice issues. In order to pursue its mission, the NIJ is guided by a set of principles. NIJ adheres to the belief that research can make a difference at both the individual and community level and can also shape a more effective and just criminal justice system. In addition, the NIJ sets in place a fair and rigorous peer review process for government-funded research. The NIJ has a research agenda that focuses on real-world issues that impact victims of crime, their communities, and practitioners. It focuses on answering research questions through rigorous testing and is supportive of innovative research methods that can lead to practical applications to better address crime.

To achieve success, NIJ partners with other agencies and organizations with shared goals

related to crime and justice. This entry reviews the organizational structure of NIJ and then discusses the priorities and activities of various offices that make up the NIJ.

Organizational Structure

NIJ is led by the Office of the Director, which consists of the principal deputy director and deputy director. These individuals report to the NIJ director who is appointed by the president of the United States. The agency's objectives are guided by the Office of the Director. However, research needs are led by the priorities of the U.S. Department of Justice. NIJ is organized into seven offices including the Office of the Director. The NIJ principal deputy director is charged with overseeing the Office of Investigative and Forensic Sciences (OIFS) and Office of Science and Technology (OST). The OST includes the Policy and Standards Division and the Research Division. The Office of the Director is also charged with overseeing the Office of Research and Evaluation (ORE), which includes the following three divisions: Crime and Crime Prevention Research Division, Justice Systems Research Division, and Violence and Victimization Research Division. The NIJ Deputy Director is charged with managing the Office of Communications, Office of Grants Management, and the Office of Operations.

Office of the Director

The NIJ Office of the Director sets the objectives of the department and works closely with staff

and other leadership across support offices. The priorities of the Director are divided into five main areas. The first priority is to strengthen science. This is done by facilitating the involvement of scientists in helping improve the administration of justice and public safety issues through research endeavors. The next priority of the Director involves increasing diversity. The aim is to broaden the field of researchers and themes studied under NIJ. Emphasis is placed on diversity with respect to race, ethnicity, and gender across the field of social and behavioral sciences. NIJ stresses its contribution to the success of the criminal justice system across the country through increasing diversity in research. The third priority of the Director involves measuring the impact of the work done by the NIJ. This involves investigating how its investments impact the criminal justice system, policies, and practices. The fourth priority involves encouraging multidisciplinary activity. The Director encourages cooperation and engagement across disciplines and agencies. Finally, the Director's priorities include fostering researcher-practitioner partnerships. This is accomplished by expanding its engagement and collaborations with practitioners.

The Office of the Director is also tasked with three major initiatives, which include issues involving the following: building the field through career development of criminal justice researchers, expanding intramural research, and improving customer service. With respect to career development, NIJ works on building and investing in the careers of researchers in the field. The opportunities, investments, and size of those investments have increased over time. To accomplish this initiative, NIJ provides opportunities for researchers, including NIJ Fellowship Programs and the NIJ Research Assistant Program. In addition to the fellowship opportunities, NIJ started an NIJ Director's Early Stage Investigator Award in 2016. This award is meant for researchers in their early career stages who are conducting primary or secondary research in criminal justice, crime control and prevention, violence and victimization.

The second initiative involves intramural research. An intramural research program supplements NIJ's extramural research program and helps to ensure the fulfillment of the mission of the

NIJ. Not only does the intramural research program serve to complement the extramural research program, but it helps to advance and form the extramural research efforts and identify gaps in technology and research. The goal is to improve criminal justice outcomes such as public safety.

The third initiative is to improve customer service. The Office of the Director aims to meet the needs of its grantees, research community, practitioners, and policy makers. To address the needs of its grantees, NIJ set up the Office of Grants and Management. This specialized office is tasked with providing guidelines to award recipients through the life cycle of their grant. In addition to managing the aforementioned priorities and incentives, the Office of the Director oversees the OIFS, the OST, and the ORE.

OIFS

The NIJ OIFS is the leading federal agency charged with forensic science-related research as well as the programs and trainings related to this field. In addition, it is responsible for improving laboratory efficiency and addressing issues related to backlogs. The mission of this department is to improve forensic sciences through research, development, technology, testing, and evaluation. It also creates training resources for criminal justice researchers and practitioners.

The department's major responsibilities can be broken down into three areas. First is research and development. Next is capacity building and technical assistance, followed by collaboration with peers, practitioners, and policy makers. OIFS collaborates with peers across academia, government, and private industry. It offers workshops and meetings to develop research and evaluation activities with policy makers and practitioners. The organizational structure of OIFS includes the Office Director, Associate Office Director, and the Research and Technology Support Division.

OST

The NIJ OST is the leading agency working on criminal justice-related technology. Its mission is to use technology and technology-related knowledge to make improvements upon criminal justice policies and practices. To accomplish this goal,

OST conducts research and testing and evaluation of technology-related issues. It also develops equipment for these purposes, manages that equipment, and assesses how it is used. Finally, OST informs policy makers about how the technology can be used for criminal justice-related purposes. OST works with its staff, scientists, and engineers by using both extramural and intramural research practices.

OST is guided by four major activities that revolve around technology and technology-based advances that are applied to the criminal justice system. The first major activity relates to research and development. Its research and development process follows guidelines that align with NIJ practices. However, the research and development for OST undergoes four phases. First, OST makes technology-related needs decisions based on engagement with practitioners. Next, it develops plans that address the needs of the practitioner community. This is followed by developing solutions. Finally, it tests and evaluates those proposed solutions.

OST's second major activity involves standards development and conformity assessment. This program supports the publication of equipment standards that are unique to law enforcement agents and other criminal justice agents. OST develops and publishes equipment standards in order to address issues related to equipment safety, reliability, and requirements.

The third major activity revolves around national law enforcement and corrections technology. OST manages centers that serve to inform NIJ's research activities and support new tools and practices. Finally, OST focuses on collaborations with peers, practitioners, and policy makers across government, academic, and industry. These relationships and collaborations are a primary focus of OST.

OST is organized into two divisions: the Research Division and the Policy and Standards Division. The Research Division is responsible for research, testing, and evaluating projects and activities related to tools and technologies used by criminal justice practitioners. The Policy and Standards Division is tasked with research, testing, and evaluating activities associated with new or improved technologies as well as equipment standards and assessment programs.

OREs

ORE is the third department headed by the Office of the Director at NIJ. ORE is charged with developing and supervising research activities that aim to prevent and reduce crime and violence. Topics examined include the justice system, criminal justice issues, crime prevention, and violence and victimization.

ORE is also charged with various activities, including research, development, and evaluation. Similar to the other offices, this department focuses on advancing knowledge in the field of criminal justice for practitioners and policy makers alike. There is an established order for the research and development process, which includes the following six steps: identifying needs, developing a research agenda, implementing the research, engaging in monitoring activities after grants are awarded, evaluating results of the research, and disseminating the results of the research. The research focus of ORE is diverse and can touch on several aspects of the criminal justice field.

There is also a focus on emerging trends and established programs. Some of the major research programs of ORE include the Violence Against Women Program, which focuses on researching issues related to teen dating violence, stalking, sexual assault issues, and intimate partner violence. The program aims to spread knowledge regarding tools that can be used to reduce violence against women, teens, and girls. Some of the emerging trends in the research include issues related to longitudinal examination of violence and victimization.

Another major activity of ORE involves collaborating with policy makers, peers, and practitioners to address issues in the criminal justice system. Regular meetings occur between scientists and stakeholders to discuss future research and address emerging trends in the criminal justice field.

ORE encompasses the following three divisions: Violence and Victimization Research Division, Justice Systems Research Division, and the Crime and Crime Prevention Research Division. The Violence and Victimization Research Division focuses on intimate partner violence, sexual assault, human trafficking, stalking, childhood exposure to violence, and elder abuse. The Justice

Systems Research Division focuses on policing, courts and corrections, race/ethnicity and crime, and drugs and crime. The Crime and Crime Prevention Research Division focuses on school safety, gangs, firearms, white-collar crimes, and other substantive areas.

Deputy Director

The NIJ Deputy Director oversees the following three offices: Office of Operations, Office of Grants and Management, and the Office of Communications. The Office of Operations provides support to lines of business, which includes administrative support services, audits, budget issues, and other business-related matters. The Office of Grants Management administers and manages grants. The Office of Communications focuses on publishing and conducting outreach and conferences.

NATIVE AMERICAN TRIBAL COURTS

Native American (American Indian and Alaskan Native) tribal courts are grounded in the principle of sovereignty. Many of the more than 500 tribes recognized by the U.S. federal government have courts for the adjudication of civil and criminal cases. These courts vary in their judicial range and authority and are semiautonomous, consistent with their tribes' histories and limited right to self-government. Accordingly, generalizations concerning their structure and function are unhelpful. To varying extents, the courts reflect the influence of both Native American cultures and

European traditions of jurisprudence. They are subject to the limits imposed by federal law, and state jurisdiction is also authorized under some circumstances.

Early views of Native Americans as racially inferior to Whites endured in stereotypes reinforced by the use of Western psychiatric classification systems and assessment methods. More recent conceptualizations reflect respect for traditional aboriginal ways. Mental health interventions have become more collaborative and diverse, notably Tribal Healing to Wellness Courts. Mental health issues relevant to tribal legal proceedings include historical trauma as well as the heightened risk of Native Americans for substance abuse, sexual assault, and suicide relative to the general U.S. population.

History

The pre-Columbian aboriginal population of North America was nearly annihilated by diseases that were spread through their early contacts with Europeans. American Indian tribes were further reduced by wars and outright slaughter and damaged by policies—forced relocation and acculturation—that disrupted their societies and traditions. According to the 2010 U.S. Census, 1.7% of the U.S. population, 5.2 million persons, were Native American alone or in combination with one or more other races. As of 2017, there were 567 Indian tribes recognized by the U.S. federal government.

In signing treaties with aboriginal tribes on the North American continent, the British government legally recognized their sovereign status. This status was further acknowledged in the U.S. Constitution, and for nearly a century after the American Revolution, the U.S. government continued to negotiate and sign treaties with various tribes, although these were invariably violated by the government or by White settlers.

Early U.S. Supreme Court decisions also helped create the framework for the legal relationships of tribes, states, and the federal government. Notably, in *Worcester v. Georgia*, 31 U.S. 515 (1832), the majority held that the Cherokee tribe was a *Nation*, unbound by the laws of Georgia and subject only to those of the federal government. The first Courts of Indian Offenses, the forerunners of

Native American tribal courts, were established by the Bureau of Indian Affairs in the 1880s. Some are still in existence, although most have since been replaced by courts established by the tribes themselves, as permitted under the Indian Reorganization Act of 1934. The act also gave tribes on reservations the right to adopt constitutions and to incorporate.

Current Status

Tribal court jurisdiction fundamentally pertains to Indian country, consisting of reservation lands, Indian trust allotments, and dependent Indian communities. As of 2017, 175 Native American tribes operate tribal courts. Courts of Indian Offenses still exist in some parts of Indian country, mostly in Oklahoma. Due to their respective tribes' sovereignty, cultural histories, and the varying impact of statutes and case law, current tribal court systems are quite variable, with some structured more like traditional U.S. courts, having tribal prosecutors and defense advocates, while others have more informal systems, including alternative litigation tracks within tribal courts or alternative courts, such as the Navajo Peacemaker Court.

There are adult, juvenile, family, and wildlife conservation tribal courts. Indigenous forums (e.g., sentencing circles, council of elders, peacemaking) operate at a level below tribal courts and serve a dispute resolution function. Some tribal courts provide alternatives to incarceration, including probation, drug and alcohol rehabilitation, counseling, fines, restitution, and community service. Judges may be popularly elected or appointed, typically, in the latter case, by the tribal council. Many appellate courts have been established, and the Seminole Nation of Oklahoma has a supreme court. Tribal police serve as first responders for major crimes and misdemeanors. In civil matters, tribal courts have sole jurisdiction concerning claims arising in Indian country against a tribal member and brought by any person.

With respect to criminal law, jurisdictional matters are complex and subject to change. Public Law 83-280 (Public Law 280) gives six states—Alaska, California, Minnesota, Nebraska, Oregon, and Wisconsin—jurisdiction over criminal and civil offenses committed against or by Native

Americans in Indian country within those states, with some exceptions. In the remaining states, tribal authority is shared with the federal government, although Public Law 280 gives these states the right, whether exercised or not, to assume concurrent law enforcement authority.

In non-Public Law 280 states, discretion regarding the prosecution of major crimes falls under federal jurisdiction. Federal prosecutors may elect to prosecute major crime cases or turn them over to state jurisdiction. Minor crimes involving Native American perpetrators and victims fall under tribal jurisdiction, and in those cases involving only non-Native Americans, the state has the authority.

As of 2016, there were 80 jails in Indian country housing a total of about 2,540 inmates. Most are located in states west of the Mississippi River, with Arizona having the greatest number of these facilities, at 21, and several states having only 1 facility each. Where tribal courts' sentencing authority is ordinarily capped at 1 year, pursuant to the Tribal Law and Order Act of 2010, they have the authority to sentence selected offenders to up to 3 years' incarceration in Indian country correctional institutions. On average, in 2016, jails in Indian country operated at 62% of rated capacity. Native Americans accused or convicted of crimes that fall outside the purview of tribal law and courts (those committed outside Indian country, and, generally, felonies) may be confined in non-Native American jails or state or federal prisons.

Related Mental Health Issues

Medicalized Racial Bias, Coerced Assimilation, and Historical Trauma

Mental health-care scholars and providers concerned with tribal criminal justice matters would benefit from an understanding of the historical framework in which beliefs about Native American pathology have been generated. Nineteenth-century phrenology texts portrayed Native Americans as intellectually and psychologically inferior to Whites, lending a pseudoscientific veneer of credibility to these stereotypes. During the early 20th century, anthropologists began studying Native American cultures and tribe members. However, their research was

compromised by Eurocentric biases, that is, viewing Native American customs from the standpoint of White culture, including the use of tests and techniques such as the Minnesota Multiphasic Personality Inventory and Rorschach. These instruments were not normed or standardized on these populations, so their use effectively reinforced these crude racial constructions. It was only decades later that social and behavioral scientists began to understand the flaws in their methods and attempt a more culture-fair approach, a process that continues as part of a more general appreciation of and respect for ethnic and cultural diversity by the social and behavioral sciences.

Beginning in the late 19th century, as outright war between Whites and Native Americans drew to an end, and sympathy within the dominant culture increased toward remaining Native Americans, the Indian boarding school movement promoted forced acculturation. By government authorization, Native American children were removed, sometimes forcibly, from their homes and sent to boarding schools. In these institutions, now mostly closed, tribal languages, religion, and other aspects of their cultures were suppressed. Many Native American children were abused or died of infectious disease there.

Related Native American Mental Health Concerns

The victimization—through war, disease, dislocation, and intentional cultural destruction—of Native American tribes over the course of centuries has given rise to what has been termed *historical trauma*. This is chronic, collective, and transgenerational psychological disturbance that does not square readily with diagnostic categories in orthodox psychiatric classification systems, such as the *Diagnostic and Statistical Manual of Mental Disorders*, meant to define individual psychopathology.

Native Americans are at increased risk of emotional and behavioral disorders. Suicide rates for Native Americans are the highest for any racial group in the United States. Rates of substance abuse for Native Americans are also relatively high, and the criminal justice system generates nearly half of adult Native American substance abuse treatment admissions. Native Americans are

more likely than members of any other race to be the victims of violent crime. Native Americans aged 12 years and older are twice as likely as the general population to be the victims of rape or sexual assault. These outcomes speak to the need for using appropriate screening and intervention procedures for Native Americans, including those involved with the criminal justice system, and then to implement culturally appropriate and effective therapeutic measures.

Tribal Healing to Wellness Courts

One particularly notable development with respect to the criminal justice system is the Tribal Healing to Wellness Court. Created with the support of the federal government and with input from tribal leaders, and with attention to the diverse needs of the various tribes, these courts are adaptations of the drug court model. Such courts have been implemented in more than 120 Native American communities. They can serve a diversion function, that is, as an alternative to incarceration, in adult, juvenile, and family courts. While Native Americans collectively constitute an understudied population, the Tribal Healing to Wellness Court model supports the utilization of evidence-based interventions.

Future Directions

Tribal courts and the larger criminal justice system in which they function will continue to be shaped by statute, case law, and American Indian/Alaskan Native tradition. With the Native American population growing at a rate faster than that of the general U.S. population, tribal courts will face new and complex challenges requiring substantial resources. The Department of Justice administers the Coordinated Tribal Assistance Solicitation, through which it funds a range of criminal justice and public safety initiatives (e.g., alcohol and substance abuse interventions) through grants. The Office of Juvenile Justice and Delinquency Prevention prioritizes programming on behalf of Native American youth. Since 2002, the Bureau of Justice Statistics periodically administers the National Survey of Tribal Court Systems in partnership with several public agencies and law schools, gathering data on tribal justice systems, including

probation, pretrial and indigent defense services, and juvenile cases. Scholars, practitioners, and policy makers can use this information to support continued improvements in the functioning of Native American tribal courts.

Partnerships with academic institutions are also important. For example, several law schools operate Indian law clinics, providing consultation services regarding tribal laws, codes, and regulations, as well as training lawyers to specialize in Native American legal issues. The Indian Country Child Trauma Center at the University of Oklahoma Health Sciences Center is staffed by a small group of psychologists. Their mission is to develop targeted, culturally appropriate, outreach, and service delivery materials with an emphasis on dealing with the effects of trauma for Native American children and their families.

Reliable and adequate funding sources, along with culturally sensitive collaborations between Native American and non-Native American agencies and institutions, will be critical to the functioning of Native American tribal courts and to the well-being of the persons under their custody, care, and control.

NEED PRINCIPLE

In 1990, Canadian researchers Donald Andrews, James Bonta and Robert Hoge proposed three principles that would form the foundation for all effective correctional programming. That is, they outlined the three necessary conditions needed in interventions and treatments for offenders in order to reduce risk of reoffending as well as reduce recidivism (reoffending) rates. This model is known as the *Risk-Need-Responsivity* (RNR) model of effective correctional treatment. The core of the RNR model is targeting treatment on criminogenic needs (i.e., crime-causing factors).

The risk principle identifies *who* should receive the most treatment (i.e., the most intensive treatment services should be directed to the highest risk offenders, and low-risk offenders should receive minimum intensity programming). The responsivity principle describes *how* the treatment should unfold (e.g., use empirically supported therapies such as cognitive behavioral therapy and then altering this therapy to accommodate for individual learning styles, abilities, and personality). The need principle identifies *what* should be targeted in treatment; that is, the intervention the offender receives should target that offender's criminogenic needs (i.e., changeable factors, which result in reductions in recidivism if addressed). This entry explores criminogenic needs and the role of the need principle in reducing offending and reoffending rates.

What Are Criminogenic Needs?

Criminogenic needs are a cluster of changeable factors that, if present, increase someone's

likelihood to engage in crime. Changes or fluctuations in these factors result in changes in the likelihood a person will engage in crime. As such, criminogenic needs are often referred to as *dynamic risk factors*. In 2006, Stephen C. P. Wong and Audrey Gordon defined dynamic risk factors as changeable or potentially changeable factors (e.g., substance abuse, impulsivity, criminal peers, unemployment, family discord, criminal attitudes) that can be influenced or changed by psychological, social, or physiological means such as treatment. Thus, changes in the dynamic risk factors should be linked to changes in recidivism, and measurement of an individual's current dynamic factors can determine his or her risk level and predict the likelihood of reoffending. Some examples of prominent risk assessment measures that use dynamic risk factors include, but are not limited to, the Violence Risk Scale (VRS), the Historical-Clinical-Risk-Management-20, the Level of Service Inventory-Revised, and the Level of Service/Case Management Inventory.

Given the relationship between criminogenic needs and risk to reoffend, it should not be surprising that many criminogenic needs are identified as the best predictors of future offending. The Central Eight risk factors represent the top eight strongest predictors of crime consistently documented in decades of research on crime. They include past criminal behavior, criminal personality, criminal attitudes, criminal peers, substance abuse, employment issues, marital or relationship issues, and lack of prosocial hobbies. Although other risk factors have been identified (e.g., housing problems, emotion dysregulation, mental health issues), the Central Eight remain the best predictors of risk to reoffend as well as actual reoffending. Most of the risk factors listed are potentially changeable (i.e., dynamic) through treatment or intervention (e.g., cognitive therapy to change attitudes, training and education to reduce employment issues, social skills and effective communication training for marital issues, and addiction treatment for substance abuse issues).

When correctional treatment is focused on criminogenic needs, reductions in risk and reoffending rates are observed. However, it should be noted that when treatment programs do not focus on criminogenic needs but on noncriminogenic

needs (i.e., treatment targets that do not have a direct relationship with inducing criminal behavior such as self-esteem or vague emotional concerns), such programs have been seen to have either no effect on reoffending rates or an increase in reoffending rates. Thus, effective offender rehabilitation must focus on criminogenic needs as a primary goal of treatment, and the role of treating noncriminogenic needs may best relate to increasing treatment engagement, building motivation, establishing the therapeutic alliance, or the removal of barriers that may impact the individual's ability to benefit from need-focused treatment (i.e., the treatment of noncriminogenic needs is a responsivity issue).

Does Targeting Criminogenic Needs in Treatment Result in Reduced Offending?

Since the introduction of the RNR model, a plethora of studies have supported its use as a treatment model. In 2006, Andrews and Craig Dowden examined the importance of the risk principle in correctional treatment. The researchers found solid support for the utility of the risk principle in correctional programming; that is, when treatments adhered to the risk principle (targeting high-risk offenders with the most intensive treatment), a 10% reduction in reoffending was observed. When the risk principle was adhered to in programs that also followed the responsivity principle, a 26% reduction in reoffending was observed.

Adherence to the need principle in correctional treatment has some of the strongest support. In 2000, Dowden and Andrews examined the need principle in violent offenders. Treatment programs that focused on criminogenic needs were associated with reductions in reoffending rates ranging from 26% to 43% depending on type of reoffending (i.e., violent vs. property vs. drug offenses). When all three RNR principles are implemented in treatment, reoffending rates decreased by up to 52%. Interestingly, programs that did not adhere to any of the RNR principles were associated with increases in reoffending of up to 10%. Thus, support for the RNR model, and the need principle in particular, is strong and has been shown to be useful in the treatment of most offender populations and offense types (including young offenders,

women offenders, and minority offenders as well as to violent offending, gangs, offending inside the prison, and sexual offending).

Do Changes on Tools of Criminogenic Needs Translate to Reduced Reoffending Rates?

A growing number of risk assessment tools include dynamic risk factors; however, the majority of research conducted on these measures has examined the relationship between reoffending and scores on dynamic risk factors at a single time point. As noted by Robert Karl Hanson and Andrew Harris in 2000, to make claims of dynamism, a minimum of two ratings are required at different time points. In other words, claims that a particular risk factor is dynamic must be supported by research showing that such factors do change, that these changes can be reliably measured, and that these changes reflect actual changes in reoffending rates. Up until recently, many hypothetically dynamic risk factors (criminogenic needs) did not have such research support; however, new research has begun to demonstrate that dynamic risk factors do change with treatment, that these changes can be measured reliably, and that these changes do reflect real reductions in reoffending rates.

Demonstrating the connection between changes in dynamic risk factors (due to treatment) and changes in reoffending has largely been neglected in empirical research. Preliminary attempts to address this hole in the literature have examined dynamic risk variables at multiple time points. For example, in 2002, Henrik Belfrage and Kevin S. Douglas examined the dynamic variables' scores on the Historical-Clinical-Risk-Management-20 in forensic psychiatric inpatients before and after treatment. The researchers demonstrated that movement on the dynamic variables did occur following treatment. However, the researchers did not examine whether the change on the dynamic variables translated to a change in reoffending rates as they did not have a follow-up period.

Risk assessment instruments specifically designed to assess change in dynamic risk factors have been developed. Both the VRS and VRS: Sex Offender edition (VRS:SO) contain dynamic risk factors and use an integrated stages-of-change model to assess change. Change scores on the

dynamic risk factors of the VRS and the VRS:SO have been shown to be associated with reductions in general, violent, and sexually violent reoffending. For example, study by Kathy Lewis and colleagues in 2013 found support for the predictive importance of using changes in dynamic risk scores. The researchers examined the predictive validity of the VRS in a sample of 150 adult, male, high-risk, highly psychopathic violent offenders who completed a high-intensity cognitive behavioral therapy-based violence-reduction treatment program. Mean total follow-up time was roughly 5 years. The researchers found that reductions in dynamic risk scores over treatment were associated with similar reductions in violent reoffending during the follow-up period. Specifically, prosocial changes (i.e., reductions in criminogenic needs as measured by the VRS) were associated with reductions in future violence. Furthermore, offenders with large reductions in dynamic risk scores (greater than 7 points of change) had less than half the recidivism rate than offenders with low change scores (less than 3 points of change). Moreover, after controlling for important confounding variables, the likelihood of the offender being convicted for a new violent offense decreased by 8–13% for every one point reduction in dynamic risk factors (criminogenic needs).

It appears that changes in criminogenic needs can be reliably measured, that these criminogenic needs do change over the course of treatment, and that these changes reflect real-world reductions in reoffending rates (even in psychopathic offenders). Furthermore, such findings support the underpinnings of the need principle and the underlying presumptions of all correctional rehabilitation.

The Future of the Need Principle

Research on the need principle, criminogenic needs, and dynamic risk factors has been widely positive. Such research continues to build confidence in the utilization of the RNR model to effectively rehabilitate offenders. However, much progress is left in the pursuit of maximizing correctional assessment and treatment effectiveness.

In 2005, in a unique study, Daryl G. Kroner, Jeremy F. Mills, and John R. Reddon conducted a *coffee can* analysis of four commonly used risk assessment tools. Individual risk factors from the

four tools were transcribed onto separate cards. The cards were mixed in a coffee can, and then items were drawn at random to create four new instruments comprising randomly selected items from the original tools. Upon creating the randomly generated instruments from the original four tools, the researchers demonstrated that no single original risk assessment tool had better predictive ability for future reoffending than any of the coffee can tools. The researchers interpreted the results in two ways. First, the results supported that all four measures had similar predictive accuracy for future criminal offending, suggesting that the focus on assessing and treating criminogenic needs is well supported. Second, the results demonstrate a failing of current risk assessment theory and point out deficiencies (or opportunities) in the conceptualization of dynamic risk. Thus, the researchers argue that assessment of criminogenic needs is being conducted under a stagnated conceptualization of risk and that advances in the development of a criminogenic need constructs are needed. In other words, although the use of criminogenic needs has provided many benefits to correctional assessment and treatment, new developments in the area of criminogenic needs are greatly needed to push forward and further improve correctional assessment and treatment.

Many potential research avenues have been identified in the research literature to help expand understanding of the need principle, only some of which are noted here. Additional research on why some offenders do not benefit from RNR-based treatment is needed. Furthermore, understanding why some offenders drop out of RNR-based treatment is important for maximizing the treatment effectiveness and reductions in reoffending. On a related note, why some offenders maintain their treatment gains after RNR-based treatment whereas other offenders backtrack and return to their old levels of dynamic risk requires further attention. Moreover, what is the role of probation and community supervision in promoting and maintaining reductions in criminogenic needs. Furthermore, the role of protective factors and their interactions with criminogenic needs warrant clarification. With ongoing study of all these variables, scholars will better understand the relationship between the need principle and the

process that offenders go through in their attempts to desist from crime.

NEIGHBORHOOD AND CRIME

Crime is often concentrated in geographic locales such as neighborhoods. Crime rates in neighborhoods tend to be consistent over time, yet rates can vary greatly between neighborhoods. Factors at the neighborhood level such as poverty, racial makeup, single-parent households, and residential mobility rates are often correlated with crime and criminal activity. Crime and criminal behavior is commonly associated with individual-level factors such as age, gender, substance use, and antisocial traits. However, neighborhood-level factors are equally important in understanding crime rates in geographic areas. By including neighborhood-level factors in crime analyses, researchers can understand the structural factors that may impact individual-level factors and contribute to overall crime. This perspective provides alternative solutions for reducing crime rather than only arrest and incarceration for individual offenders. This entry discusses formal and informal social control, social disorganization theory, collective efficacy,

coercive mobility, broken windows theory, deviant culture, and racial and economic segregation as they relate to neighborhood and crime. This entry ends with a brief discussion of the methodological challenges in studying the association between neighborhood and crime.

Formal and Informal Social Control

Social control is how societies, organizations, neighborhoods, or any kind of group ensures that its members follow established norms and rules and behave in an ordered way. Formal social control is enacted by police officers, courts, and other social actors, like child welfare workers, who formally sanction individuals for violating laws. Sanctions take the form of counseling or educational classes, probation, or incarceration. Informal social control is enacted by group members to admonish, chastise, or otherwise address the behaviors of other group members whose actions violate group norms, expectations, or laws. Examples of informal social control include a teacher reprimanding students for not waiting for their turn or not raising their hand before speaking, a neighbor admonishing teens for loitering on the street corner, and a minister counseling a parishioner. This informal social control creates expectations and norms for behavior through both disseminations of information and active intervention in addressing behavior that falls outside of expected norms. When informal social control breaks down, norm violations and unlawful activity occur. Most explanations for why neighborhoods and crime are associated are concerned with the breakdown of informal social control at the neighborhood level.

Social Disorganization Theory

Social disorganization theory posits that residential instability, low socioeconomic status, and ethnic-racial heterogeneity in a neighborhood represent social disorganization, which contributes to a lack of communication and shared values in its residents, leading to an inability to address problems in the community. This social disorganization allows crime and delinquency to flourish in these neighborhoods. Residential instability is the movement in and out of neighborhoods, and

ethnic-racial heterogeneity is the diversity of race or ethnicity in a neighborhood; these factors can lead to a loss of communication and shared values among neighbors, resulting in social disorganization. This ecological theory arose from observations that juvenile delinquency persisted in some neighborhoods despite changes in the racial and ethnic composition of the neighborhood over time.

Later theories of social disorganization introduced the idea of social control as the mediating factor between social disorganization and crime. In this model, friendship networks, participation in local organizations, and unsupervised peer groups represent the amount of social control in a neighborhood and contribute directly to crime. Additional structural factors such as urbanization and family disruption were added to the previous structural factors of residential instability, socioeconomic status, and racial-ethnic heterogeneity as constructs of social disorganization. This social disorganization contributes to weak social networks, low participation in local organizations and institutions, and unsupervised teens, which in turn leads to crime.

Extensions of social disorganization theory have included concepts such as social ties, social capital, formal social control, culture, and urban political economy as possible important components of social disorganization. Overall, there has been mixed empirical support for these additions to the theory.

Collective Efficacy

Building on social disorganization theory is collective efficacy, which is the ability for neighborhoods to engage in purposeful action to address deviance and crime. This is enacted not only through informal social control on its residents, especially juveniles, but also through community mobilization around issues of safety. This sense of collective efficacy is established through the formation of social cohesion and trust, which is supported by social networks and social support established between residents. Residents do not have to maintain close social ties, but more importantly there is shared belief that others share the same values, are willing to help each other, and can be trusted. For example, residents who believe that fellow residents will enact informal social

control to curtail delinquent behavior among teens or fight for services for the neighborhood have higher rates of collective efficacy. Neighborhoods with high collective efficacy are able to overcome components of social disorganization such as concentrated disadvantage and residential instability in controlling crime.

Coercive Mobility

Another extension of social disorganization theory considers the impact of formal social control, incarceration rates, and corresponding release rates from jail and prison back into a community on neighborhood crime. The removal of individuals in the neighborhood due to incarceration and their return to the community upon release is called *coercive mobility*. Coercive mobility is another type of residential instability that is the direct result of formal social control in the form of public safety policies, mainly incarceration. This adds to the overall residential instability in a neighborhood that can further erode informal social control as neighbors feel isolated from each other, social integration is low between newcomers and stayers, and a sense of commitment to the neighborhood is undermined by a feeling of impermanence.

While removing individuals who are committing crimes from a neighborhood should improve the neighborhood through removal of the unsafe element and improving social cohesion among those not offending, there may be a point when the gains from more incarceration are negated by the effects of coercive mobility, especially when individuals removed from a neighborhood due to incarceration tend to return to the same neighborhood upon release. Furthermore, as incarceration rates tend to be highly concentrated within certain neighborhoods, the effects of coercive mobility may be felt more acutely in these neighborhoods. For example, in neighborhoods with high formal control, the belief in informal control as a means to deter crime may be undermined. In turn, the erosion of informal social control can lead to more crime.

Broken Windows

Broken windows theory links urban decay and minor forms of public disorder with crime and

criminal activity. Visibly noticed phenomena such as graffiti, abandoned properties, and litter serve as signs that residents are unresponsive to low levels of rule-breaking. The belief is that this permissiveness toward low-level disorder leads to more serious criminal offending. In an attempt to prevent more serious offending, formal social control takes the place of informal social control in that police officers spend much time and energy attending to low-level behaviors like trespassing, loitering, graffiti, and minor drug possession. The logic is that engaging in swift and certain punishment for low-level offenses through arrests helps to prevent more serious offending.

Deviant Culture

Deviant culture stems from the belief that deviance is a learned behavior and individuals, especially teens, engage in deviant behavior through exposure to antisocial attitudes, values, and norms. Deviance and antisocial attitudes are culturally transmitted through exposure to others who engage in these behaviors and possess these attitudes. There are two major explanations for deviant culture: cultural heterogeneity and cultural attenuation. Cultural heterogeneity is when youth are exposed to both prosocial and antisocial behaviors and attitudes within a community. This dual exposure is more likely to happen in neighborhoods with concentrated disadvantage, whereas youth in middle-class neighborhoods are not exposed to the antisocial perspective. Cultural attenuation occurs in disadvantaged neighborhoods with high social isolation where a subculture of violence may seem more of the norm. This orientation attenuates the neighborhood normative values that results in the inability of the community to execute informal social control and contributes to social disorganization.

Racial and Economic Segregation

Crime rates differ greatly in neighborhoods within the same city. On a surface level, these differences can be attributed to the racial makeup of the neighborhoods, with Black communities experiencing the highest crime rates and White neighborhoods experiencing the lowest crime rates. However, this explanation ignores other important factors contributing

to neighborhood racial differences in crime. Theories highlight the ways U.S. society is structured around race, with the dominant group acquiring and maintaining privileged positions, and the reproduction of these hierarchies throughout the major institutions in the United States such as schools, labor market, criminal justice, and health care contributes to social and economic disadvantage within the nondominant groups. One prime example of this is residential segregation in which years of policies that privileged Whites in the housing market produced practices such as redlining, real estate blockbusting, and predatory housing loans that have resulted in extreme racial residential segregation. This residential segregation along with society's structures results in the racial-spatial divide in which racial and ethnic minorities live in inner-city disadvantaged neighborhoods and have the worst prospects for educational and employment opportunities. These practices have led to neighborhoods organized by race with neighborhoods of color experiencing more disadvantages, leading to more crime. However, higher crime rates in these neighborhoods may also be the result of location of the neighborhood itself, with higher crime neighborhoods embedded in disadvantaged areas, which also experience structural disadvantage. Conversely, White neighborhoods experience low internal disadvantage and are likely to be embedded in a context of other advantaged neighborhoods, amplifying the effects of residential segregation.

Methodological Challenges

There are many methodological challenges in studying neighborhood and crime. Neighborhoods can be defined in many different ways, even by individuals living in the same geographic locations. Researchers have used census block designations or other administrative agency boundaries in defining neighborhoods, but this can be problematic as these boundaries may not correspond with how individuals within neighborhoods use and perceive them. In addition, there are similar problems with how other concepts are defined and measured. There have been inconsistencies in the operational definitions of important constructs, making comparisons across studies difficult.

Another methodological challenge for studying neighborhoods is potential selection bias, that

individuals prone to criminal activity select to live in certain neighborhoods and it is the individuals, not the neighborhood effects, who contribute to crime.

Finally, testing the theories of neighborhood and crime, like social disorganization theory, has always been a methodological challenge as the theory was first developed before there was the ability to accurately analyze multilevel phenomena. While research methodologies have advanced, there are still many challenges in unraveling exactly how social disorganization impacts crime.

NEIGHBORHOOD EFFECTS, THEORY OF

The theory of neighborhood effects focuses on the impact of neighborhood factors on individual offending. This perspective places people within the context of their community to explain antisocial behavior. Neighborhoods have the ability to impact individual behavior through opportunities to commit crime, child development, and the acquisition of values that may direct behavior. This entry begins with a discussion of the perspective's evolution and some of the pathways through which communities are believed to influence individual offending. It also discusses the impact of neighborhoods on the motivation to offend as well as protective community factors and interactions between neighborhood and individual characteristics.

Development of the Perspective

This area of study has grown substantially since the 1990s, largely due to advances in statistical techniques and an increase in the availability of data that includes individual and neighborhood characteristics. While there has been substantial growth in this area, the majority of studies in criminology focus on either individuals or neighborhoods separately. However, focusing only on individuals or neighborhoods is problematic because it is not possible to draw conclusions about individual behavior by focusing on only neighborhood factors, nor is it possible to draw inferences about neighborhood crime rates based on the behavior of individuals. By bringing both of these aspects together, the theory of neighborhood effects allows for an assessment of how individual and neighborhood characteristics together produce individual antisocial behavior.

Neighborhood Pathways to Individual Offending

Per-Olof Wikström and Robert Sampson argue that criminal behavior is due to the environment in which individuals find themselves coupled with their propensity to offend. The decision to offend is due to a combination of individual and situational factors, with people differing in how

favorably they view the environment for offending. Communities are seen as backdrops for behavior and have the ability to encourage or discourage criminal behavior. The extent to which a neighborhood encourages criminal behavior is a function of the levels of temptation, provocation, and deterrence in that neighborhood. Individuals differ in their exposure to neighborhood settings that encourage criminal behavior as well as their offending propensity. Thus, individuals residing in communities with higher levels of temptation and provocation and lower levels of deterrence should have an increased likelihood of engaging in criminal behavior. Furthermore, according to Wikström and Sampson, neighborhoods have the ability to impact an individual's propensity to offend directly and indirectly through developmental processes that act as antecedent influences on criminal behavior.

Neighborhood Influences on the Motivation and Propensity to Offend

Stress–Strain Perspective

Communities can produce stress or strain on individuals and thus have the ability to stimulate delinquent behavior—particularly through economic deprivation, levels of crime, and disorder. Disorder can include graffiti, abandoned buildings, drug markets, prostitution, and other general neighborhood signs of decline. In 2011, Holly Foster and Jeanne Brooks-Gunn conducted a review of neighborhood influences on behavior in children and adolescents, generally finding support for the argument that communities can increase delinquency, aggression, and conduct disorders. Neighborhood stressors or strains found to lead to greater levels of individual delinquency and antisocial behavior included poverty, disadvantage, neighborhood disorder, and concerns for safety. In addition, while neighborhood stressors had a direct impact on individual behavior, they also had an indirect effect. Specifically, neighborhood stressors (e.g., economic disadvantage) impacted families, parental mental health, and parenting practices, which in turn can shape the development and behavior of children and adolescents over the life course.

Low Self-Control

According to Michael Gottfredson and Travis Hirschi, one characteristic that is formed during childhood and remains relatively stable through an individual's life is the individual's level of self-control. Low levels of self-control have been consistently linked to an individual's propensity to offend. Self-control should play an important role when considering the option of committing a criminal offense as opposed to prosocial alternative behaviors. Those who are more impulsive may be less likely to consider alternative behaviors as well as the negative repercussions of offending. Thus, individuals with low self-control should be more likely to engage in criminal behavior. The origins of self-control have been argued to be the product of either biological elements or parenting practices or a combination of these factors. However, Wikström and Sampson claim that community factors also influence levels of self-control both directly and through their impact on family processes. While some support has been found for their argument, research on the direct impact of neighborhood conditions on self-control has been mixed.

Code of the Streets

Another way community characteristics can increase criminal offending is through the development of a subculture that supports delinquent values. According to Elijah Anderson, a *code of the street* has developed in African American communities characterized by high levels of disadvantage and crime. This code is a response to those conditions and even acts to regulate violence. This includes providing a rationale for violent acts to be committed in an approved context. In communities characterized by a greater belief in the code of the street, there is an overall distrust of the criminal justice system, and settling issues through violence is viewed more favorably than contacting the police or through other nonviolent means. Anderson argued that violent behavior by individuals can result in respect from those who follow the code of the street and reduce the risk of victimization, while a failure to engage in violent behavior when challenged may increase the risk of victimization. Thus, even those who do not specifically

value violent behavior are required to be knowledgeable of the code of the street to prevent victimization.

Mark Berg and Eric Stewart's review of the street culture literature provides support for many of Anderson's arguments. For example, a study in 2006 by Eric Stewart and Ronald Simons found that higher levels of community disadvantage and crime strengthened individuals' beliefs in the street code, which partially mediated the impact of these conditions on individual violence. A separate study by Stewart and Simons found that the code of the street as a larger neighborhood subculture increased the violence of individuals, regardless of their belief in the code, and produced greater violence among individuals who followed the street code.

Neighborhood Protective Factors

In 1997, Robert Sampson, Stephen Raudenbush, and Felton Earls argued that collective efficacy has the ability to protect a community and the individuals within from high levels of crime. With its roots in the social disorganization literature, collective efficacy is described as mutual trust and cohesion among neighbors as well as a willingness to intervene for the common good. Communities high in efficacy are generally close-knit and trusting, while also made up of residents who would intervene when children engage in delinquent behavior. Concentrated disadvantage, crime, and immigrant concentration have been found to be related to lower levels of collective efficacy at the neighborhood level, while residential stability has been connected to higher levels. Collective efficacy should work to reduce criminal and delinquent behavior through the socialization of neighborhood youths when they are outside the home and in the community, by monitoring unsupervised groups of adolescents and public spaces, as well as limiting neighborhood disorder. The protective effects of collective efficacy are largely informal and do not rely on those outside the community or government agencies such as the police to intervene and solve problems.

Collective efficacy has been shown to be directly related to lower levels of crime in communities, even mediating the effects of other neighborhood factors, such as concentrated disadvantage and

crime. At the individual level, it is related to lower levels of antisocial behavior for younger children in deprived contexts, domestic violence, unstructured or unmonitored socializing with peers, and socializing with delinquent peers. Collective efficacy has also been found to positively impact parenting quality. However, while adolescents might be deterred from committing crime in the high collective efficacy neighborhoods where they reside, Sampson suggests these individuals may shift their criminal activity to neighborhoods with lower levels of collective efficacy.

Person–Neighborhood Interactions

Neighborhoods have been found to moderate traits that influence the propensity to offend. However, this research is mixed with some studies finding that neighborhoods with weakened protective factors (e.g., cohesion and informal social control) or greater risk factors (e.g., economic disadvantage) show a stronger relationship between impulsivity or self-control and delinquency. In contrast, some researchers have found the opposite. For example, Gregory Zimmerman found that self-control contributed less to offending in neighborhoods with greater risk factors, and the effect of self-control was stronger in neighborhoods with greater protective factors. In these cases, it may be that it is difficult for anyone in high-risk communities to avoid criminal activity, regardless of personal characteristics, whereas those with low self-control who reside in low-risk communities are less likely to be impacted by protective neighborhood characteristics.

Similarly, the research on the effect of peers on delinquency at varying levels of neighborhood risk is somewhat inconsistent. A 2011 study by Gregory Zimmerman and Steven Messner found that the effect of peer violence on individual violence was greater in neighborhoods with lower levels of disadvantage. This may be due to individuals in disadvantaged communities having higher levels of exposure to peer violence, and after a certain point, an increase in exposure is unlikely to lead to greater offending. However, another study found that the effect of neighborhood risk factors on delinquency is greater in the presence of delinquent peers and that prosocial peers reduce the impact of neighborhood risk on delinquency.

Overall, the research suggests that certain community conditions, such as neighborhood disadvantage, impact the behavior of individuals either directly or indirectly through other means, including parenting and the adoption of antisocial attitudes. While there are neighborhood risk factors that may encourage offending, there are also protective aspects such as collective efficacy. Developments in biosocial criminology suggest that protective and hostile neighborhood factors may also be relevant for individuals possessing certain genetic characteristics. Furthermore, other research has begun to address individual factors that impact selection into neighborhoods. As of 2016, there is still uncertainty about the impact of neighborhood conditions and how they amplify or buffer the effect of individual characteristics and the causal mechanisms through which neighborhood conditions influence individual behavior, with a number of conflicting findings across studies. Further research on the relationship between communities and individual offending should eventually yield more consistent results and a greater understanding of the effects of neighborhoods on deviance among individuals.

ÑETA

Ñeta is an international Puerto Rican prison and street gang. Although there is not a consensus on how to identify prison and street gangs, Ñeta features several identifiers that a gang typically possesses: Its members engage in criminal behavior inside and outside prisons, it has an organizational hierarchy and strict rules, and it uses several types of symbolic colors and words to illustrate membership. This entry on Ñeta provides an overview of the association, including information on its history, meaning of its name, symbols and rituals, organizational structure, and ends by reviewing some law enforcement criticisms of the association.

Ñeta, also known as *Ñetas*, *Asociación Ñeta* in Spanish, or “Association Ñeta” in English, began as a prison gang that evolved into a street gang and continues to grow and spread throughout the world as a criminal enterprise. It has been characterized as a prisoners’ rights group, an inmates’ rights movement, and a pro-inmate rights association, even identifying as *Asociación Pro-Derecho*

Al Confinando, which translates to the “Pro-Rights Association.” In addition, as a Puerto Rican group, it is known to be sympathetic to ideas of political independence for Puerto Rico and political recognition from the U.S. government.

However, the National Institute of Corrections and the National Gang Crime Research Center have identified Ñeta as a security threat group, which is typically defined as a group of at least three people who conspire to engage in fear, intimidation, and disruptive and criminal acts. Although Ñeta’s membership originated in Puerto Rico, it is now global; its membership is estimated at tens of thousands of members in Puerto Rico and in the United States and approximately 10,000 members in other parts of the world including Asia and Latin America. As is typical of gangs, tracking definitive membership numbers is difficult because the association is secretive about members, and there is a sophisticated vetting process for recruits. In the United States, Ñeta primarily resides in the Northeast, including New Jersey, New York, and the rest of New England.

History

Ñeta was formed in the late 1970s by Carlos Torrez Irriarte, also known as *La Sombra*, or the Shade and Maximum Leader, and other Puerto Rican prisoners in Oso Blanco Maximum Security Prison, which is located in Rio Piedras, San Juan, and Puerto Rico. In the 1970s, the Oso Blanco prison system was understaffed and overcrowded. Early members of Ñeta claim the group was born out of the necessity for survival in the violent prison environment. Because of a lack of guards, prisoners governed themselves, and survivability rested on the formation of gangs for protection.

Before Ñeta was founded, the Puerto Rican prisons were controlled by *Grupo 27* (Group 27). Ñeta formed to combat *Grupo 27* (whom it called *Insectos*) and the abuses of non-gang-affiliated prisoners. In other words, Ñeta’s formation was intended to provide a mutual protection group against *Grupo 27*. Members of Ñeta united against *Grupo 27* because *Grupo 27* became powerful and preyed on new prisoners. Irriarte and others were threatened and disagreed with *Grupo 27* policies and practices, such as the rape of other prisoners and theft. On March 30, 1981, Irriarte

was killed by *Grupo 27* to stop Ñeta's growth. Ñeta retaliated and murdered the leader of *Grupo 27*. The legend and notoriety of Ñeta grew when members dismembered the *Grupo 27* leader and mailed his body parts to prison administrations and his mother as a sign of its power.

By the early 1990s, Ñeta had spread to prisons in the United States including Attica, San Quentin, Auburn, and many prisons in New York City and the state of New Jersey. In the 1990s, Ñeta members, upon parole from prison, spread Ñeta to the streets of the United States, and within a few years, Ñeta street gang members established themselves in several illegal economic ventures on the East Coast. By quickly recruiting outside of prisons, the street gang members extended Ñeta's reach even more. The police in the areas where Ñeta is established have documented that the association claimed it was *community based* while simultaneously participating in illegal lucrative tasks such as selling illegal narcotics.

Meaning of Ñeta

The origin of the name Ñeta possibly comes from the Taino language of the indigenous Taino Indians, who resided on the island of Puerto Rico, among other regions. During the Taino baptism, the baptized child was called Ñeta, which meant "warrior" or "new birth." Ñeta is also an acronym for Never Ever Tolerate Abuse, reflecting the political cause of prisoner's rights, pro-independence, as well as a moniker for the prison and street gang.

The letters NDC, meaning *Ñeta de Corazon* (heart of Ñeta), are associated with Ñeta and often seen in graffiti or in tattoos on members. A heart tattoo and "1.50" or "150%" are also found in graffiti, writings, or tattoos, symbolizing the 150% effort members pledge for the association.

Ñeta Symbols

The gang's colors are red, white, blue, and sometimes black. The colors are representative of the Puerto Rican flag, but black is sometimes substituted for blue in clothing and regalia. Ñeta members also incorporate P.R. (Puerto Rico) into their clothing and often display the Puerto Rican flag.

Roman Catholicism, which is the predominant religion in Puerto Rico, has a continued influence on Ñeta. Like other Latino gangs, Ñeta employs the use of Catholic rosary beads as symbols of the gang; the rosary beads are worn by members as a visual affiliation of Ñeta membership, with various colored patterns having distinct meanings. For example, a probationary member wears all white beads until full membership is granted. Full members wear black, red, and white beads. The numbers and colors of the rosary beads also carry meanings for Ñeta members. The 78 white beads represent the boroughs of Puerto Rico, the seven black beads represent the seven Puerto Rican prisons where Ñeta's founding took place; red beads represent the gang's bloodshed, whereas green represents the sacred; and the cross is symbolic of Jesus Christ, whom Ñeta members claim presides over all of them.

The gang's hand sign is the index finger crossed with the middle finger. The two fingers represent their unity, and the remaining ring and pinky finger pointed down represent the disrespect of law enforcement or prison administrations and also their rival gangs and enemies. Ñeta members salute each other by showing their gang sign with their hand and placing that hand over their heart. Ñeta members also refer to each other as *hermanitos* and *hermanitas* (brothers and sisters) because they view members as family.

Structure System

The organizational structure of Ñeta is very secretive, as members are prohibited from discussing organizational matters with nonmembers. In addition to the first and second in command, leadership positions include the organizer, who tracks and keeps notes of Ñeta's meetings, the *vocal*, who is the spokesperson for the gang membership, and the disciplinarian, who dictates reprimands for members who violate gang rules. The voting population in Ñeta is known as the *pueblo*. Leaders are voted in or out of their position by the pueblo.

Ñeta calls court and produces its own *legal documents*, which is paperwork used to inform Ñeta of criminal informants or snitches or other serious breaches and allegations. The association also relies on approximately 25 *norms* to guide gang behavior. A few examples of these norms

include respecting the leader's decisions, not disrespecting any member's mother, and following proper reporting channels if they feel a fellow member is being dishonest, unfaithful, or disrespecting the norms or the gang.

Rituals

Ñeta employs certain types of rituals. For example, in meetings of the association, a chant titled *El Grito* (meaning "the shout") is invoked in which all members chant *Ñeta* several times with one designated person shouting *asociación* before the members shout *Ñeta*. New members are called *seeds* from their tree of recruitment and are sponsored by *Ñeta* members for a 30-day trial, during which they are taught *Ñeta*'s history. Upon admittance, the seeds sign an oath of allegiance to *Ñeta*, swearing their life to the association. March 30, the anniversary of founder Carlos Torrez Irriarte's death, is viewed as a sacred day. This day is a day not only to commemorate Irriarte's contribution in creating the association but also for remembering other deceased *Ñeta* members.

Law Enforcement and Correctional Criticisms

Law enforcement criticisms of *Ñeta* focus on *Ñeta*'s claims that it is a cultural group that promotes Puerto Rican culture as well as a prisoners' rights group. Although there is some truth to these claims, law enforcement notes that *Ñeta* is engaged in illegal activities such as drug activity, violence, extortion, and murder, and *Ñeta* members have been known to be employed as hitmen for other prison and street gangs.

The Puerto Rican government has also expressed concern regarding *Ñeta*'s association with *Los Macheteros*, a Puerto Rican revolutionary group also known as the "Boricua Popular Army" that campaigns heavily for Puerto Rican independence through clandestine military operations. Some prominent rivals of *Ñeta* in the gang's territories are the Latin Kings, MS-13, and Los Solidos.

NEUROBIOLOGICAL BASES OF AGGRESSION

Aggression might best be defined broadly as an expression or action intended to harm another. The closely related notion of violence refers to a physical or possibly a psychological attempt to harm another. Various criminal codes provide relatively nuanced guidelines concerning boundaries across which expressions of harm become criminal offenses. Psychologists have traditionally examined aggression from different perspectives through legal (e.g., murder, assault), motivational (e.g., sexual assault, revenge), personal (e.g., psychopathy), or situational (e.g., proactive, reactive) lenses. More recently, some researchers have reported differential characteristics of brain structure and blood flow in different criminal types. This entry presents an alternate viewpoint that attempts to integrate these diverse perspectives into a coherent psychobiological model, that is, the biological basis of behavior and mental processes.

Background

Psychobiological approaches attempt to understand different types of behavior as expressed information processing that occurs at hierarchical levels of brain organization. Meaningful behaviors contain contributions from five information-processing dimensions that collectively can be said to define psychological space. These begin with

perception of an immediate environment subsequently interpreted by *cognitive*, *motivational*, and *emotional networks*. Ultimately, cognition achieves a one-to-one correspondence between its elements. Motivation networks focus attention on aspects of the environment that can furnish either immediate or delayed gratification or reward (including feeding, fleeing, fighting, and sex). Emotional systems act as *amplifiers* for selected aspects of the environment that overfocus on the emotionally salient elements and deflect attention from other potentially relevant and important stimuli. Basic emotions can be grouped into those that favor *approach* (e.g., happiness, surprise, anger) and avoidance (e.g., fear, disgust, sadness). Cognition, motivation, and emotional systems interact, resulting in complex processing systems that are integrated, leading to a decision about a particular course of action that is outputted as a *motor response* or the behavior in question.

Individual processing differences in perception, cognition, motivation, and emotion make the decision-making process very complex. They also explain why traditional stimulus-response accounts of behavior in all but highly controlled environments are simplistic and unable to account for more complex behaviors including aggression. Specifically, different individuals can aggress or not aggress in identical situations and for idiosyncratic reasons.

Psychobiological Aggression Model

In 1968, K. E. Moyer introduced a system for classifying aggression that stimulated considerable research into basic neurobiological processes in rats and cats. These include predatory, defensive, irritable, territorial, maternal (i.e., protective), and inter-male (i.e., sexual contest) types of aggression. Important toward appreciating this classification system is that absent some form of brain damage or anomalies in hormonal processes, the potential for all of these aggression types resides within everybody. Individuals differ in their threshold for aggression within each of the component systems necessary to meet or exceed the trigger threshold of a given system.

Further complicating this picture, each of the major processing systems is controlled by a connected regulation system in the brain, typically in

the frontal lobes. Consequently, violent response patterns and termination characteristics are also specific to different aggression types. Each of the systems involved has dedicated neuroanatomical, neurotransmitter, and receptor subtypes associated with their operation.

Aggression Types and Overt Behavioral Patterns

In general, predatory aggression is motivationally driven, *recruiting* the cognitive system to facilitate attainment of a physical goal. Consistently, only the required minimum amount of violence is applied to achieve the goal, and goal attainment terminates the aggressive act. Irritable aggression is delivered in an envelope of anger or rage, and the severity of violence is typically out of proportion to the eliciting stimulus. In some cases of domestic violence, an individual becomes frustrated with a boss or coworker, inhibits a violent response at work but comes home to find dinner 3 minutes late, and brutally assaults the spouse until exhaustion sets in. Similarly, instances of *overkill* involve anger- or rage-based aggression. Defensive (or fear-initiated) aggression is also *reactive*, but its purpose is to incapacitate a threat, at least long enough to escape (the so-called flight-or-fight syndrome). When the threat is escapable or neutralized, the aggression ceases. Territorial aggression in the animal kingdom functions to protect turf necessary to furnish resources necessary for survival including food sources and females. Gangs similarly mark their borders, and members of other gangs can walk in peace across a street but can be killed for straying across some designated line in the asphalt. Figure 1 summarizes the triggering and behavioral patterns of the different aggression types.

Neurobiology of Predatory Aggression

For predatory aggression, opportunity for immediate gratification initiates activation of the brain's primary reward system. Specifically, this consists of the neural tract connecting regions embedded deep in the brain, specifically the ventral tegmental area (VTA) with the nucleus accumbens. The primary neurotransmitter (i.e., chemical messengers responsible for transmitting electrical

Figure 1 Aggression Typology

impulses between brain cells) involved in the reward system is dopamine (DA). Two DA receptor subtypes are involved in enhancing the rewarding effect of DA transmission in the VTA-nucleus accumbens tract. D_1 receptors function to maintain attentional focus on the source of gratification, while DA_2 receptors function to inhibit access of potentially competing information from ongoing VTA-nucleus accumbens reward signaling. In addition, internally manufactured opioids (i.e., substances involved in pain relief that create a state of euphoria) are located in the VTA and interact to enhance the rewarding experience, thereby further biasing decision-making to favor an intense rewarding experience. Other substances such as testosterone and the amino acid neurotransmitter, glutamate, facilitate the process.

Two different pathways inhibit the DA reward pathway. These reflect distinct psychological experiences, reflecting two almost opposite personality characteristics. The first involves the serotonin (5-hydroxytryptamine or 5-HT for short) pathway between a brain region termed the *raphe nucleus* that produces 5-HT and the VTA where 5-HT inhibits DA. This lessens the strength of DA activation and lessens the likelihood of pursuing the immediate gratification option. This also affords

the individual the ability to *stop and think* about the negative long-term consequences that in most situations would outweigh the fleeting value of immediate gratification. In general, strong emotional states (e.g., anger/rage, fear/panic) inhibit cognitive functioning, while motivational states focus cognitive functioning to achieve the identified goal. 5-HT also has an inhibitory influence on testosterone, reducing the likelihood of impulsive predatory aggression, but in a different way.

A second inhibitory pathway for predatory aggression involves the fear/stress system (see Neurobiology of Defensive or Fear-Based Aggression subsection). Individuals prone to quick and intense activation of the anxiety/fear/stress pathway avoid aggressive choices not because they stop and think about the long-term negative consequences, but because the involved risk activates fear-associated inhibition of reward-seeking processing.

A principal brain pathway for controlling motivational decision-making (i.e., balancing immediate vs. long-term considerations) involves the ventromedial prefrontal cortex, the underside region of the frontal lobe. Injuries to the ventromedial prefrontal cortex and its neighboring orbital prefrontal cortex (located just above the

eyes) often result in disinhibition in the face of opportunities for immediate reward that would include predatory aggression.

Neurobiology of Irritable or Anger-Based Aggression

The amygdala is an almond-shaped brain structure charged in general with processing emotions and assigning emotional values or *tags* (e.g., anger) to previously neutral stimuli. The brain pathway involves neural projections to the thalamus (akin to a relay station in the middle of the brain) from where it is sent to both the amygdala (for an immediate emotional assessment) and also to the prefrontal cortex (for a slower and *later* cognitive appraisal). Ongoing amygdala activity can interfere with prefrontal activity and at least partially explains why individuals experiencing intense anger or rage typically react in counterproductive ways, without consideration of longer term costs to themselves or the victim. Other substances such as testosterone and the neurotransmitters epinephrine and norepinephrine serve to energize the body and focus behavior on the target of the anger.

Neurobiology of Defensive or Fear-Based Aggression

With respect to fear processing, fearful perceptions enter the amygdala and branch out to different regions within it. Fear processing in the amygdala is controlled in part by the dorsal medial prefrontal cortex. When a potentially threatening stimulus is perceived, epinephrine and norepinephrine are immediately released by the inner region of the adrenal glands (adrenal medulla) from activation of the sympathetic nervous system. If the stress is prolonged, a chemical pathway then triggers the release of the stress hormone, cortisol, from the outermost region of the adrenal glands. Cortisol then creates negative psychological states, anxiety/fear/stress, and inhibits DA and testosterone influence. Fear-related information is transferred from the amygdala through a neural circuit to the spinal cord where it also activates the autonomic nervous system, resulting in characteristic changes in blood pressure, heart rate, perspiration, and pupil dilation.

Prefrontal Cortex and Regulation of Aggression

It is well established that specific information-processing functions are housed within the left and right hemispheres, which, respectively, include the primary aspects of language and spatial processing. Similarly, accumulating research evidence suggests that active processing of anger (which is deemed a negative emotion) involves more left-sided PFC activity. The approach–avoidance laterality model argues that the left PFC processes approach biases while the right PFC favors avoidance biases. From a clinical neuropsychological perspective, this may explain why cases of right PFC injury result in disinhibited and uber-reward-focused behaviors while left PFC injuries result in avoidance and apathy.

This laterality might be used to further understand aspects of the different types of aggression from a neurobiologically informed, information-processing vantage point. Briefly, predatory aggression (classified by some as *proactive* or goal-directed aggression) clearly involves an approach to the intended victim and inflicting the necessary violence in service of attaining the tangible reward—anything that might range from money to sex. This type of decision-making approach involves greater activation of the right PFC relative to the left PFC.

A similar argument but involving a very different trigger (e.g., frustration, insult) can be made for the *reactive* irritable or anger-based aggression type. In this case, an irate individual approaches the source of frustration or insult with the violence that eventually causes the anger to subside. However, the *reactive* defensive or fear-based aggression type initially aims to escape or avoid the situation and should involve activation of the left PFC. Indeed, this presents an initial dilemma because if the purpose of defensive or fear-based aggression is to avoid the aggressor and activate the avoidance response, how can defensive or fear-based aggression ever occur? It may be that a two-step process is involved. The first step consists of the goal of escaping the threat and not approaching the aggressor at all, leading to a cognitive appraisal of the likelihood of success of an escape plan. If feasible, flight is the first option, and no or minimal confrontation with the threat occurs. However, if the escape plan appears unlikely to succeed, Step 2 begins and irritable aggression

results. This might explain why in at least some instances of defensive or fear-based aggression, the intensity of violence exceeds what would reasonably be necessary to permit an escape.

Implications for Violent Risk Assessment and Interventions

There are several advantages to applying a neurobiological approach to risk assessment of offenders in the real world. At the behavioral descriptive level, regardless of whether one utilizes static or dynamic variables, it is logical to develop predictors for a more specific type of behavior than for a broader group that contains separable subgroups. However, this approach affords the opportunity to use existing neuropsychological tests (i.e., behavioral and mental activities designed to measure brain functions) to examine the functioning of a particular offender's ability to control his or her cognitive, motivational, and emotional processes. These need not be seen as stand-alone predictors but can be integrated with the offender's criminal history to examine possible links between a specific problem in brain functioning measured by the test and the expected types of aggressive incidents in the offender's criminal record.

In the future, it may be possible to record signals from brain cells or even activity within the blood while offenders are undergoing neuropsychological testing. Because different individuals can succeed or fail a task for different reasons, ongoing recordings of brain activity would afford the forensic psychologist the ability to evaluate objectively important brain-based phenomena such as the laterality of task processing, alertness levels, atypical waves, motivational and emotional states, and attention and effort levels. These neural recordings may provide a baseline for comparison with how the individual performs the tasks, and whether the individual's physiological markers are the same or move into an improved direction after administration of an appropriate intervention.

NEUROBIOLOGICAL MODELS OF PSYCHOPATHY

In contemporary academic and clinical parlance, *psychopathy* refers to a personality disorder characterized by a combination of affective, interpersonal, lifestyle, and behavioral elements. Specific psychopathic traits include glib superficiality, callous lack of empathy, a conning and manipulative interpersonal style, poor behavioral controls, and impulsivity, among others. These traits emerge early in childhood (assessed as early as 5 years old), progressing to chronic interpersonal instability and antisocial behavior through adulthood. For individuals meeting full clinical criteria for psychopathy, these traits are found in many domains of their life and remain remarkably stable across the life span.

The current clinical standard for evaluating psychopathy is based on an expert-rater device, the Hare Psychopathy Checklist–Revised (Hare PCL-R). The Hare PCL-R requires extensive collateral source review (i.e., social worker reports, police reports, psychiatric observations) and a detailed case history interview. The Hare PCL-R

was developed primarily for the evaluation of psychopathy among adults in forensic settings. Derivatives of this measure include a youth version and a briefer screening version, primarily for use with psychiatric patients. Many additional measures have been developed to evaluate psychopathic symptoms, including self-report instruments typically used in non-forensic settings. The consistency of measurement across the expert-rater and self-report instruments is typically poor, requiring consumers of the literature to carefully attend to which assessment instrument was used. The most consistent neurobiological findings are found in studies using expert-rater devices (i.e., Hare PCL-R, PCL-youth version).

Importantly, psychopathy is distinct from antisocial personality disorder (APD) as assessed by the *Diagnostic and Statistical Manual of Mental Disorders* (DSM). As many scientists have noted, the difference between the Hare PCL-R and the DSM APD conceptualization of psychopathy is that the latter fails to adequately assess the interpersonal and affective symptoms defined in the clinical tradition dating back hundreds of years. The DSM APD conceptualization also heavily relies on frequent antisocial behavior as a symptom, and this behavior does not sufficiently characterize the breadth of psychopathic traits. Moreover, there are many distinct routes and motivations underlying antisocial deviance, most of which do not involve psychopathic personality. Thus, most people who meet criteria for psychopathy using the Hare PCL-R will also meet criteria for DSM APD, but only a small portion (20–30%) of those who meet criteria for APD will also meet criteria for psychopathy using the Hare PCL-R. In sum, psychopathy as embodied by the Hare PCL-R is not the same as the construct of APD defined by the DSM. This neurobiological review focuses on studies that employed the Hare PCL-R.

Neurobiological Models

Psychopathy is widely recognized as a developmental disorder with a strong genetic influence that produces rather specific neurocognitive deficits. Several models have emphasized the importance of different cognitive features in promoting psychopathic traits. Despite some variation in form, these models converge in implicating a

cohesive network of brain areas responsible for the integration of emotional processing into higher order cognition. Here, the most prominent models that have contributed to improving understanding of the neurobiological origins of psychopathy are described.

The Prefrontal Cortex and Pseudo-Psychopathy

The earliest accounts of how the brain can influence maladaptive social behavior arose at a time when medical science was first discovering these brain-behavior relationships—mostly through accounts of focal brain injuries and their consequences. A prominent historical example is that of Phineas Gage, a 19th-century American railroad worker who survived a catastrophic injury to the frontal portions of his brain, reportedly causing drastic changes in his behavior and personality, which included newly acquired impulsivity, aggression, and promiscuity. The details of this case study have recently come under critical scrutiny; nonetheless, he remains a prominent figure in the history of neuroscience. It stands as a symbol of the evolving understanding of the role the brain plays in determining complex social behavior.

There have been several more recent and well-corroborated accounts of focal brain injuries to the orbitofrontal/ventromedial prefrontal cortex resulting in behavioral changes that mimic certain aspects of psychopathy. The presentation of poor moral judgment and lack of behavioral controls following injuries to the ventromedial and orbitofrontal cortex have sometimes been called *pseudo-psychopathy* in neuropsychological literature. It should be noted, however, that the consequences of prefrontal damage more often produce only mild dysfunction, which can be highly variable. The role of the ventromedial prefrontal cortex is generally described as integrating emotion-cognition interactions. That is, it plays a role in weighing the value of rewards and punishments and monitors behavior based on these evaluations. When severe deficits in behavioral control and apparent lapses in judgment are present, these symptoms still do not account for the full spectrum of traits that constitute psychopathy. Thus, the presentation of *pseudo-psychopathy* following

a brain injury is both exceedingly rare and, more generally, a misnomer. Still, the ventromedial prefrontal cortex plays a prominent role in contemporary neurobiological models of psychopathy, but it is not alone in this influence.

The Amygdala and Fear

Another prominent trait among psychopaths is an apparent absence of anxiety and a lack of aversion to some things that most healthy individuals would actively avoid. Behaviorally, this can present as a failure to anticipate or avoid behaviors with assured consequences. These characteristics helped to promote an early model of psychopathy called the *low-fear hypothesis*. A great deal of early psychophysiological research supported the notion that psychopaths showed reductions in certain physiological responses during the anticipation of punishment and when faced with aversive stimuli. Accumulating evidence has demonstrated, however, that this model is somewhat underspecified. Rather than lacking fear, it may be more appropriate to describe psychopaths as failing to utilize emotional cues (i.e., punishment cues) to modify their ongoing behavior.

The amygdala is located bilaterally in the anterior medial temporal lobe—very near the center of the brain. The amygdala is prominently associated with brain activity related to distress, anxiety, and threat detection, so it has also featured prominently in many neurobiological models of psychopathy. However, the amygdala is not *only* involved in threat detection. More generically, it is important for encoding stimulus-reinforcement contingencies. That is, the amygdala helps to detect the value of a stimulus that should promote further action due to its motivational importance. In short, the amygdala serves to amplify any exogenous stimulus into higher cognitive processing that may be of critical importance.

Neurobiological research clearly indicates that the amygdala is impaired in psychopathy, as demonstrated during a variety of tasks, such as reinforcement conditioning and passive avoidance learning. Patients who suffer focal brain lesions to the amygdala due to injury or disease do not suddenly acquire psychopathic traits. Rather, the consequences of these rare lesions promote rather specific deficits impairing perception of social

cues and facial emotion, emotional episodic memory, and the evaluation of stimulus-reinforcement contingencies. Again, these deficits do not fully account for the full spectrum of psychopathy. It is reasonable to suspect that, occurring at an early age, they may promote more complex manifestations of psychopathy by impairing critical developmental trajectories in social cognition.

Additional evidence of amygdala impairment comes from structural MRI studies of individuals with clinical levels of psychopathic traits. These studies find robust amygdala volume and density deficits in large diverse samples of males and females, adults and adolescents. Indeed, structural MRI deficits in the amygdala is one of the most replicable findings in the psychopathy literature.

Integrated Emotion Systems

Combined findings of orbital frontal cortex and amygdala dysfunction in psychopathy led to the development of the *integrated emotion systems* model of psychopathy. This model highlights reduced unconditioned reinforcement evaluations (e.g., responding to facial cues), impaired acquisition of reinforcement contingencies (pairing actions with reward and punishment), and determining expected value (e.g., predicting the outcomes of their behavior). These critical forms of learning are supported by the amygdala and ventromedial prefrontal cortex along with other closely associated brain areas such as the insula, striatum, and dorsomedial prefrontal cortex. The consequences of such dysfunction interfere with the long-range efficacy of emotional learning for guiding behavior and future planning.

A critical step in understanding psychopathy has been clarifying the specific cognitive mechanisms responsible for the functional deficits consistently documented in this disorder. Furthermore, it is important to recognize that the wide range of cognitive and behavioral abnormalities apparent in psychopathy cannot be accounted for by dysfunction in a single brain region. The integrated emotion systems model provides a thorough account of these diverse functional deficits and further proposes a likely developmental course that gives rise to these impairments. In short, reduced responsiveness to unconditioned aversive

stimuli, impaired aversive conditioning, and disrupted stimulus-reinforcement learning are all potentially detrimental to socialization, and together, they are likely to promote patterns of antisocial behavior.

Paralimbic System Dysfunction

No brain area operates in isolation. Each focal impairment in psychopathy will produce extended downstream consequences in the brain, and these downstream effects produce the myriad subtle impairments in cognition and behavior that characterize psychopathy. Predicting the extent of these downstream consequences requires an appeal to how brain areas are structurally and functionally connected. The *paralimbic dysfunction* model of psychopathy is grounded in the cytoarchitectonics of the brain, that is, similarities in cellular structure that help researchers understand the functional relatedness of many brain structures. The paralimbic system describes a structurally interconnected and functionally related network of brain areas that include the amygdala and orbital frontal cortex (i.e., ventral medial prefrontal cortex), cingulate cortex (anterior and posterior), parahippocampal areas, the insula, and portions of the anterior temporal lobes. These brain areas work together to support a range of cognitive functions aimed at incorporating fundamental drives (aversions and appetites) with higher order cognition (planning and decision-making).

The paralimbic dysfunction model of psychopathy hypothesizes that this entire network is ultimately compromised in psychopathy. While dysfunction in the amygdala and medial prefrontal cortex is relatively robust and evident in a wide variety of experimental manipulations, extended deficits are often subtle and more contextually specific. Observing these complex downstream consequences requires large sample sizes, careful quantification of psychopathic traits, and precise experimental manipulations. Indeed, large-sample investigations of psychopathy have revealed structural and functional abnormalities extending into this entire network of interconnected brain areas. The consequences of these abnormalities can help account for the wide range of deficits attributable to psychopathy.

Attention and Emotion

The previous sections describe the wide array of brain areas that have shown structural and functional differences related to psychopathy. The consequences of these abnormalities are imprinted on brain systems governing motivation, attention, decision-making, and behavioral control. An additional model that focuses on dynamic features of attention has gained prominent support from behavioral and neuroscientific investigations. The *response modulation* model suggests that psychopaths are capable of processing emotional information adequately when it is their sole focus of attention. However, when features in a complex, naturalistic environment compete for cognitive resources, psychopaths show an inability to reallocate attention to stimuli with value that supersedes their original focus. That is, if a specific focus of attention has already been established, psychopaths show difficulty adaptively redistributing their cognitive resources to incorporate new information. An important consequence of these deficits is that psychopaths' cognitive abnormalities extend beyond the processing of emotional stimuli.

It is overly simplistic to suggest that emotion and attention are separate features of cognition. Rather, emotional salience may be thought of as one of many mechanisms of attention. Attention-based models of psychopathy do not negate findings of emotional processing deficits. They generalize and extend these deficits to more fundamental attributes of cognition.

Final Thoughts

As the conceptualization and measurement of psychopathic features have become more specific and reliable, so have descriptions of the underlying neural properties that support these features. Contemporary neurobiological descriptions of psychopathy now suggest that dysfunctional properties of the brain extend to the entire paralimbic system. Developmental perspectives have described how specific deficits in aversive responses and reinforcement learning can disrupt socialization and promote antisocial behavior. Cognitive models of psychopathy extend these consequences to a more generalized impairment in recognizing and integrating salient information,

which diminishes psychopaths' capacity to adaptively adjust their behavior. The understanding of psychopathy at a neurobiological level has improved dramatically in the past decade, and continuing advancements in neuroscientific approaches promise to add even more clarity to these models in the years ahead.

NEURODEVELOPMENTAL DISORDERS IN INCARCERATED OFFENDERS, TREATMENT OF

High rates of neurodevelopmental disorders have been found within the criminal justice system. Neurodevelopmental disorders are a group of disorders in which the development of the central nervous system is disturbed, which can be

manifested as neuropsychiatric problems or impaired motor function, learning, language, or nonverbal communication. According to the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5)*, the standard classification of mental disorders used by mental health professionals in the United States—an entire class of disorders that are usually diagnosed in the earlier developmental stages of the human life course, including intellectual/learning disability, autism spectrum disorder (ASD), and attention-deficit/hyperactivity disorder (ADHD)—are outlined under the umbrella term *neurodevelopmental disorders*. Historically, these disorders were thought of as first occurring in childhood or as exclusive to childhood. However, it is now apparent that these early-occurring disorders continue into adolescence and adulthood for many of those affected. In addition, these disorders may share some genetic and neurobiological risks and developmental trajectories.

Although a disproportionately high concentration of individuals with neurodevelopmental disorders are involved with the criminal justice system, the knowledge on these disorders in this population is limited. This is partly due to the difficulties in recognizing and assessing neurodevelopmental disorders in secure facilities and incarcerated settings. One reason is a lack of suitable assessment tools. In addition, although many prisoners may be able to complete a self-rating scale, others, particularly those with more severe neurodevelopmental disorders, need clarification of some of the terms used and help to understand what they are being asked. In the limited number of studies focusing on neurodevelopmental disorders in prisons, prisoners with these disorders are usually identified based on their self-report of an existing diagnosis of intellectual disability, ASD, or ADHD or their above-the-threshold scores on standardized screening assessment tools that are usually used in clinical (but not incarcerated) or nonclinical populations. For example, the Learning Disability Screening Questionnaire, the adult ADHD self-report scale, and the Autism Quotient can be used to screen for intellectual disability, ADHD, and ASD, respectively, although the reliability and validity of these screening tools among prison populations are unclear.

Intellectual Disability in Prisoners

Intellectual disability, formerly termed *mental retardation*, is a disorder with onset during the developmental period that includes both intellectual and adaptive functioning deficits. Neuropsychological measures of IQ, as indirect indices of brain function, are usually used to assess the level of intellectual deficits. The adaptive deficits, on the other hand, limit one's activities of daily life, such as communication, social participation, and independent living. Prevalence rates for intellectual disability have been estimated as approximately 1% (varying by age) of the U.S. population. In the criminal justice system across the world, depending on the study methodologies and diagnostic criteria, the prevalence may range from 0.5% to 11% in adults and much higher for prisoners younger than 18 years.

To date, studies of intellectual disabilities and crime have overall been limited and focused largely on the qualitative nature of antisocial behavior in individuals with intellectual disabilities. For example, studies found that compared to those with other mental illnesses (e.g., schizophrenia, mood disorders, epilepsy), individuals with intellectual disabilities are more likely to attack persons outside of the family and intimate social circle and less likely to attack individuals in authority—which may have been due in some way to their subordinate social status. They are also more vulnerable to aggressive and disruptive behaviors. In terms of the types of offenses, offenders with intellectual disabilities are more likely to commit property crimes, as well as sex offending and arson. Finally, they are also more likely to recidivate.

Impairments in cognitive problem-solving and impulse control might explain why individuals with intellectual disabilities commit crime. Higher levels of childhood exposure to parental aggression or physical abuse victimization have also been found in offenders with intellectual disabilities. Comorbid psychiatric conditions, such as antisocial personality disorder and substance use disorder, may also partly contribute to the origins and development of crime and violence in those with intellectual disabilities.

ASD in Prisoners

ASD is a condition marked by significant social communication and interaction deficits as well as

restricted repetitive patterns of behavior, interests, and activities. In the general population, ASD affects about 1 in 68 individuals, and the rate is estimated to be higher in prisoners and in males in general. Genetic and neurobiological disturbances, such as structural and functional brain abnormalities, may contribute to the cognitive and emotional deficits seen in individuals with ASD, which in turn increase the likelihood of their criminal behaviors.

Evidence suggests that offenders with ASD are more likely to use blunt violence, strangulation, or poison to kill victims. They are less likely to be intoxicated at the time of the offenses, and particularly more prone to stalking behaviors. They are more likely to be characterized by self-injury, aggression, and commit property damage or acts of violence. Failure to recognize emotional expressions and executive dysfunction may partly contribute to their offenses. Their lack of social competence to initiate intimate relationships and restricted interests may lead to their cravings for and persistent seeking out of intimacy, which in turn results in more stalking behaviors to certain victims.

Relatively more research has been focused on the high-functioning autism, formerly known as Asperger's disorder/syndrome. Those with Asperger's syndrome were more likely to commit arson and sexual offenses. Violence in direct response to anxiety associated with changes in the environmental or routines, to disliked stimuli such as high-pitched sounds, or preoccupations such as sex or fire, have been associated with prisoners with Asperger's disorder. Asperger's disorder has been particularly linked to cases of multiple murderers including Jeffrey Dahmer and Theodore Kaczynski. Problems of sexuality, such as public masturbation, exhibitionism, and sadism, have been reported in early studies of Asperger's disorder. Social communication deficits, including deficient empathy and lack of theory of mind, may lead to their poor relations with the opposite sex, which then in turn contributes to their sexual and nonsexual offending behavior. Finally, Asperger's disorder often co-occurs with other psychiatric conditions such as psychotic and mood disorders and Tourette's syndrome; psychiatric comorbidity may thus play a role in violent behaviors observed in individuals with Asperger's disorder.

ADHD in Prisoners

ADHD is a clinical syndrome defined in the *DSM-5* by high levels of hyperactive, impulsive, and inattentive behaviors beginning in early childhood (before age 12 years). An individual is diagnosed with ADHD when a minimum number of symptoms of either inattention (predominantly inattentive presentation) or hyperactivity-impulsivity (predominantly hyperactive-impulsive presentation) have been present for at least 6 months by the time of assessment. If an individual shows symptoms from both categories, a combined presentation occurs. Symptoms need to be present in two or more settings (such as at home, at school, or at work, with friends or relatives; in other activities) and often lasts into adulthood.

ADHD affects about 5% of children and 2.5% of adults, and the rates are higher in males than in females. While ADHD-like symptoms are found in many individuals, in people with ADHD, symptoms are severe, persistent over time, and lead to clinically significant impairments such as low self-esteem, educational and occupational problems, antisocial behavior, and problems in social interactions including coping with police interviews and court procedures. ADHD often co-occurs with ASD, specific learning disorders, substance use disorders, personality disorders, or other common mental health problems such as anxiety and depression.

Children with ADHD are at a greater risk of arrest and imprisonment during early adulthood than normally developing children, and there is a higher than expected prevalence of ADHD among adult prisoners. People with ADHD are vulnerable to engage in antisocial behavior and criminal outcomes for several reasons. First, about half of youths with ADHD will develop comorbid disruptive behavior disorders (e.g., conduct disorder and oppositional defiant disorder) that are characterized by behavioral problems that violate the rights of others and/or bring the individual into significant conflict with social norms or authority figures, and individuals with both conditions show more severe and cold-blooded types of antisocial behavior. Second, by nature of their cognitive and behavioral impairments, people with ADHD may more likely engage in offenses

that are reactive and opportunistic rather than well planned and organized, which in turn may lead to easier apprehension for their antisocial behaviors.

Once involved with the criminal justice system, these individuals are vulnerable to being unable to effectively cope with the custodial process, police interviews, and the court process. For example, when they are questioned and put under interrogative pressure, their limited ability to sustain attention over a long period of time may result in a higher likelihood to accept or comply with the suggestions of authority figures. These factors may also contribute to the reported elevated rates of false confession by people with ADHD. Once incarcerated, undiagnosed and untreated individuals with ADHD seem to have great difficulty tolerating the stress of prison life characterized by high rates of aggressive incidents, partly due to their mood instability, low frustration tolerance, and/or disorganized personality style.

Treatment Implications

Although the rate of neurodevelopmental disorders in the criminal justice system far exceeds that in the general population, the knowledge, skills, and training of forensic practitioners in these disorders are lacking. It is also important to note that in addition to those who meet diagnostic criteria for ADHD, ASD, and intellectual disability, there are individuals with broader *sub-threshold* neurodevelopmental difficulties who also have significant vulnerabilities that are likely to be exposed in prison. Many individuals with these disorders show symptoms in earlier years, although some may not be diagnosed until adulthood.

It is important for research, policy, and practice to address the needs of those with neurodevelopmental disorders and difficulties. Prison is a challenging environment for people with neurodevelopment disorders who may struggle to cope and are vulnerable to bullying. They are more likely to have comorbid problems such as mental illness including psychosis and substance misuse. In addition, they are less likely to receive evidence-based intervention in prison, partly due to the reason that people with neurodevelopmental disorders do not have the level of cognitive

functioning required to complete the program. Therefore, access to many current treatment and/or offending programs is unintentionally limited for this group if reasonable adjustments are not made.

Although attempts to find appropriate, effective services for prisoners with neurodevelopmental disorders are ongoing, some treatment approaches may be promising. For example, given the problems individuals with ASD have with recognizing others' distress, strategies such as *teaching* empathy skills may be appropriate for these individuals. Such strategies might include using individual or group treatment to attempt to develop an understanding of victims' feelings, or through role-playing or the use of computer software packages to develop an understanding of emotions. For offenders with intellectual disabilities, interventions aimed at improving competencies and skills have been recommended, including cognitive behavioral approaches and token systems. Furthermore, applications of pharmacological treatments in correctional settings have been explored for some neurodevelopmental disorders. For example, stimulants are the most common treatment for ADHD, and they have been demonstrated to be effective in the treatment of ADHD-associated aggression. Strategies targeting the aggression instead of the disorder symptoms have also shown efficacy when the severity of aggression is too high or disorder-oriented medications (i.e., antipsychotics such as risperidone or mood stabilizers such as lithium) are ineffective.

NONCONTACT SEXUAL OFFENDERS

A noncontact sexual offender is an offender who engages in criminal behavior for the purpose of sexual gratification, but there is no physical contact between the offender and the victim. Voyeurism, exhibitionism, online interaction with children, and possessing and/or viewing child pornography are examples of noncontact sexual offending. Because the media and the public generally consider child pornography to be the most serious offense of the noncontact sexual offenses, this entry focuses on the possession of child pornography as an example of a noncontact sexual offense.

In general, child pornography depicts the sexual exploitation of a minor (including the sexual abuse of a minor). However, the criminal possession of child pornography does not require physical contact between the offender who is in possession of this material and the minor who is depicted in the material. While most child pornography offenders do not sexually exploit minors in their acquisition of child pornography, they are nonetheless considered sex offenders under the law.

This entry begins with a brief discussion of what constitutes possession of child pornography in the eyes of the law, who are the offenders, and what motivates these offenders.

Possession of Child Pornography and the Law

Within the United States, the statutes or laws used to define child pornography vary among jurisdictions. Moreover, the age of consent differs between federal and state statutes. Under federal statutes, a *child* is defined as anyone under the age of 18 years, whereas in some states, a *child* is defined as anyone under the age of 16 or 17 years.

On the federal level, it is illegal for an individual to possess any amount of child pornography, even a single image or video clip, and according to the law, *possession* essentially means *accessing*. For example, simply downloading the material, but not storing it on one's computer, is a violation of the federal law. In this context, *download* includes *accessing* such as clicking on a link that triggers the appearance of the child pornographic image or video clip on the computer screen.

With regard to the state level, state laws vary in their definition of *possession* in that the definition can include (a) simple possession (i.e., for personal use) or (b) possession with intent to distribute. In some states, the distinction between the two is determined by the possession of more than one copy of a single child pornographic image. For example, in 2016, Alabama and Colorado required the possession of 3 or more copies of the same image as evidence of possession with the intent to distribute, whereas Texas required 6 or more copies, and Maine required 10 copies. In Alaska, however, possession with intent to distribute required the possession of 100 nonidentical images. In states with both types of possession, the number of copies can also determine the number of charges. For example, in Florida, a defendant in possession of 6 copies of the same child pornographic image can be charged with either a single count of possession with intent to distribute or six counts of simple possession.

The Offenders

Information about noncontact sexual offenders such as child pornography offenders is primarily based on individuals who have been arrested, convicted, or clinically treated for such offenses. Therefore, this information may not be representative of all individuals who engage in these criminal behaviors.

As with other types of offenders, including other sexual offenders, child pornography offenders are a heterogeneous group, so there is no typical profile for this type of offender. Nonetheless, there is some consensus about the demographic characteristics of child pornography offenders. For example, these offenders tend to be non-Hispanic White males, aged between 25 and 50 years, educated, of above-average intelligence, and employed. As compared to other offenders (including other sexual

offenders), child pornography offenders do not appear to have serious psychological problems or present with significant criminal histories. Information with regard to marital status suggests that at the time of their arrest, child pornography offenders are more likely to be single or have never been married. With regard to deviant sexual interests, some child pornography offenders have pedophilic interests (i.e., a sexual interest in prepubescent children), whereas others do not.

Motivations

Legal and academic discourses contend that child pornography is possessed or collected by child sexual abusers and/or pedophiles. Research, however, suggests that individuals possess this material for a variety of reasons and that the motivation can be viewed along a continuum. It has been found that some child pornography offenders seek out child pornography that is in keeping with their sexual proclivities (i.e., child pornography offenders are sexually motivated); however, it has also been found that some child pornography offenders are motivated to seek out this material for nonsexual purposes (e.g., as a result of pathological Internet use, curiosity, they are compulsive collectors in general, to alleviate negative affective states or to avoid the reality of their life). The remainder of this entry explores some of these motivations—both sexual and nonsexual.

Sexual Motivations

Fantasy-Only Offenders

This type of child pornography offender collects child pornography because the offender has a pedophilic sexual interest (i.e., a sexual interest in children). Also known as a *preferential offender*, this type of offender does not have a history of having sexual contact with children nor is the offender interested in having sexual contact with a child. The offender's involvement with child pornography is purely fantasy driven and leads no further than masturbation.

Periodically Prurient Typology

This type of child pornography offender is not exclusively sexually interested in children and

accesses child pornography because of a general sexual interest in pornography. This type of offender may have an interest in extreme forms of sex and/or whatever pornography is available. Given the varied sexual interests among offenders, this type of offender has also been labeled as *sexually indiscriminate*, *sexually omnivorous* (i.e., not primarily interested in child pornography but instead has a pornography collection that depicts a wide range of sexual activities, including child pornography), and/or *paraphilic* (i.e., having more than one deviant sexual interest).

Nonsexual Motivations

With regard to nonsexually motivated child pornography offenders, the possession of child pornography has been discussed from the perspective of Internet-enabled pathology. In this context, Internet-enabled pathology contributes to the development of deviant online experimentation. Essentially, the offender becomes bored with routine sexual themes and attempts to satiate his or her sexual desires by gradually escalating his or her Internet access to sexually inappropriate material, including child pornography.

Unlike the pedophile who has a sexual interest in children, this offender accesses child pornography because of poor impulse control and an insatiable sexual appetite. Combined, these can impel the offender to spend copious amounts of hours downloading child pornography, which can result in the possession of a significant amount of images and/or video clips. Moreover, owing to the obsessive quality of their collection, some offenders divide and subdivide their cache of child pornography into various files, according to category (e.g., physical attributes, sexual content). This is akin to what is described as the *collector syndrome*. This syndrome involves the compulsive acquisition of child pornographic material for its own sake rather than the careful selection of child pornographic material based on inappropriate sexual arousal. The offender's behavior is perceived as situational in that, if it had not been for the Internet environment (e.g., the perceived anonymity of the environment and the availability of the child pornographic material), the offender

would not have been in possession of the material.

NONCONTACT SEXUAL OFFENDING, THEORIES OF

Myriad theories have been proposed to explain why individuals engage in sex offenses. Experts from various disciplines such as psychology, biology, sociology, evolutionary psychology, and anthropology, among others, have posited theories to explain deviant sexual behavior. Predominantly, psychological, biological, and integrated theories shall be focused upon as they relate to noncontact sexual offenses.

Noncontact sexual offenders are described as those who engage in criminal acts, for sexual gratification, without physical contact to a victim. Acts of noncontact offending can include voyeurism, exhibitionism, online interaction via the Internet with children, and possessing and/or viewing child pornography. As discussed in Richard Krueger and Meg Kaplan's 2016 chapter on noncontact paraphilic sexual offenses, the gravity of noncontact offenses is emphasized by

many experts such as Gene Abel and colleagues who suggest that there is increased likelihood for noncontact paraphilias to become a *gateway* to contact offenses. Furthermore, many theories for contact sexual offending relate to causal factors for noncontact sexual offending as research suggests that there is great overlap between contact and noncontact sexual offending.

Theories for Noncontact Sexual Offending

Attachment Theory

Attachment styles form in infancy and early childhood and evolve throughout the life span. Attachment exemplifies nature and nurture working together in tandem as it is influenced by both genetic and environmental factors. This is best described by Glyn Hudson-Allez as she quotes Allen Schore as follows: "Attachment is thus the outcome of the child's genetically encoded biological (temperamental) predisposition and the particular caregiver environment" (2010, p. 34). Attachment is critical in engendering healthy emotional intimacy and sexual development. In other words, individuals who develop secure or healthy attachment early on with their caretaker (typically their mother) will be better prepared to have healthy relationships with others such as friendships as well as relationships that include sexual relations. Expansion upon the neuroscience and biological components incorporated in the development of attachment are beyond the scope of this entry; however, they are of paramount importance to understand especially in order to gain full comprehension as to what may occur in the brains of sex offenders, who typically have dysfunctional and/or insecure attachment styles.

Sexual offenders tend to have preoccupied and fearful attachment styles as they typically have negative views of self and fears of abandonment and rejection. As attachment anxiety increases, so does the likelihood of engaging in sexual offending against a child. Sex offenders are often very anxious about engaging in a romantic relationship with an adult partner. Sex offenders may engage in a relationship with a child because children are often viewed as submissive, and they do not have to worry about being rejected or abandoned by their victim. Attachment style plays a prominent role in theories regarding both contact and

noncontact sexual offending. The influence of attachment theory is present in the work of David Finkelhor, Joe Sullivan, and in the research of many other experts in the field.

Finkelhor's Precondition Model

Finkelhor's precondition model of child sexual abuse is a multifaceted model that takes situational and contextual influences into consideration. Finkelhor's model groups multiple factors into four preconditions: (1) factors related to motivations to sexually abuse, (2) overcoming internal factors, (3) overcoming external inhibitors, and (4) overcoming a child's resistance. These preconditions are typically met in a temporal fashion. Within the first precondition, factors related to motivations to sexually abuse, there are three components: emotional congruence, sexual arousal to children, and blockage.

Emotional congruence is the fit between the offender's emotional and/or sexual needs and the characteristics of the child. The second component, sexual arousal to children, is posited to be the product of inappropriate sexual experiences at a young age, such as experiencing childhood sexual abuse or being exposed to child pornography. The final motivation under this precondition is blockage. Blockage is when an offender cannot meet his or her emotional or sexual needs in an appropriate or prosocial way, so sexual offending is engaged in. This blockage may be the result of developmental blockages, such as attachment insecurity or inadequate social skills, or it may be the result of situational blockages, which may include issues such as marital problems.

The second precondition, overcoming internal factors, is strongly associated with disinhibition. In this precondition, offenders must overcome internal factors that would prevent them from engaging in sexual offending, such as the belief that producing child pornography is wrong. Cognitive distortions are a key feature of this predisposition. The first two predispositions relate to causal factors, while the last two predispositions involve the actual offense process. The third precondition consists of creating the opportunity or possibility of the offense occurring. This can involve extensively planning the offense or the offense being a crime of opportunity.

The final precondition, overcoming a child's resistance, involves having secure access to the child and/or victim. Behaviors that are typically considered grooming behaviors, such as gift giving, viewing or engaging in pornography, or threats of violence, are included in this precondition. Situations where a power relationship or immense trust is present may help facilitate these offenses.

Finkelhor's precondition model is considered one of the best multifaceted theories concerning sexual offending. Finkelhor's model takes several factors into consideration when discussing what causal factors impact an offender's developmental trajectory and choice to engage in sexual offending. This model of sexual offending has paved the road for other theories of sexual offending.

Sullivan's Spiral of Sexual Abuse

Sullivan's spiral of sexual abuse also involves four phases in the motivation of an offender's engagement in sexual offending. These phases include (1) formative factors, (2) assimilation of formative factors, (3) formulation of life theories, and (4) motivations to engage sexually with a child. Formative factors include aspects such as an individual's personal history and life experiences. All offenders indicated at least one life experience that impacted their choice to engage in the sexual exploitation of children, including childhood sexual abuse, atypical socialization, exposure to neglect, physical violence, and/or emotional abuse. Out of these experiences, childhood sexual abuse tends to be the most common and neglect is the least common.

Assimilation of formative factors can be broken down into three categories: maladaptive perceptions, activated sexual arousal, and developmental difficulties. Distorted negative views of the self were prevalent among the sex offenders. Especially common negative views included low self-esteem, a sense of inferiority, and viewing oneself as bad, unattractive, and/or weak. Activated deviant sexual arousal is associated with individuals who display these negative mood states and often come about as a product of their formative life experiences.

Biological embedding, discussed by Clyde Hertzman and Tom Boyce, is defined as "when

experience gets under the skin and alters human biological processes; systematic differences in experience in a socially partitioned environment lead to different bio-developmental states; the differences are stable and long-term; and these differences influence health, well-being, learning, and/or behavior over the life course" (2010, p. 330). Biological embedding, the process of environmental experiences altering biological functioning, can be seen in Sullivan's theory with regard to developmental difficulties.

Five common life theories that emerged within this population included the following: distorted, entitled, contaminated, selfish, and malicious. These life theories lead into the three common motivations to engage in sexual offending against children: sexual interest in children, personal affirmation, and power and control. Sexual interest in children, personal affirmation, and power and control are common themes in both noncontact and contact sexual offending. Similarities can be seen between Finkelhor's and Sullivan's work, which is why they are both viewed as some of the best theories regarding noncontact sexual offending.

Ward and Beech's Integrated Theory of Sexual Offending

Tony Ward and Anthony Beech found several plausible causes for sexual offending spanning from genetic makeup to adverse developmental experiences and attempted to complete an integrated theory of sexual offending. Their integrated theory of sexual offending (ITSO) contends that biological, environmental, and neuropsychological factors interact together to generate deviant thoughts and behaviors. ITSO posits that offending occurs as an ongoing convergence of historic and current factors that relate in a dynamic way. Biological predispositions and environmental circumstances affect the brain and create the neuropsychological foundations that make up psychological weaknesses.

Evolution, genetics, and inheritance influence biological factors to shape the sexual behaviors of an offender. Over time, the species has evolved adapting to overcome challenges in existence, but some traits can still exist in the current population, which may lead deviant behaviors. Early

species relied on indiscriminate sexual selection to mate, and this may still be an inherited trait that influences offenders.

The social and cultural environments that a person experiences as he or she develops can have an outstanding effect on later functioning in life. Distal factors, such as childhood trauma, may lead to developmental as well as psychological issues. These factors may influence the way a person perceives sexual behaviors. Proximal factors include current experiences that trigger a person's behaviors. These factors can include lack of secure attachment, rejection by a sexual interest, and/or substance abuse.

ITSO utilizes all three theories to gain a greater understanding of sexual offenders. It can serve as a framework to understand noncontact sexual offending with many of the other aforementioned theories as it employs some of the same techniques. Used as a tool for assessment and treatment, ITSO may be able to facilitate improved knowledge of all aspects of development to better assist offenders and prevent recidivism.

Crossover Offenders

Seto and Eke's Later Offending

In their 2005 study, Michael Seto and Angela Eke examined the likelihood of recidivism in offenders who possessed child pornography. In their sample of child pornography offenders, 17% reoffended in the follow-up period. Their finding suggested that offenders with a criminal history were most likely to recidivate as well as offenders who had been convicted for contact sexual crimes in comparison to those who had a criminal history composed of noncontact sexual crimes. Eke, Seto, and Jennette Williams later extended the study in 2011; results suggested that 34% of the offender sample had reoffended, with 6% committing contact offenses.

Crossover Offending

Findings from Jessi Owens and colleagues' 2016 study suggested a high frequency rate of crossover offending between contact sexual offenders and those who possess child pornography. Of those offenders who possessed child pornography, 38% also participated in contact sexual

offenses against a child. Pornography is a stimulus for sexual gratification, and results from Owen and colleagues' study suggested that the content of the pornography may also highlight the offender's sexual preferences and indicate future victim characteristics.

Research

Theories for sexual offending are multifaceted and interdisciplinary, including biological, environmental, and psychological factors. Furthermore, there is still a dearth of research on noncontact offenders and offenses especially with respect to paraphilias; therefore, further research is called for. It is hypothesized that theories that assist in isolating variables in an offender may enhance greater understanding of sexual offending. The seriousness of noncontact offenses is underscored, especially given the increased likelihood for noncontact offenses to serve in some cases as the first step toward violent and/or potentially more egregious offenses. Increased awareness of the severity and gravity of noncontact offenses may help inform as well as improve treatment, assessment, prevention, and intervention initiatives.

"NOTHING WORKS" DEBATE

The everyday phrase *nothing works* has taken on a particular significance in criminal justice, affecting practice, policy, and research in the field, with particular relevance to the question of offender rehabilitation and the reduction of criminal recidivism. Also often known as the *what works* debate, this debate refers to one of the core questions in criminology, penology, and criminal psychology: that of whether or not individuals who have broken the law, and especially those who have done so on repeated occasions or who have committed serious crimes, are likely to do so on subsequent occasions—and what approaches if any society can use in trying to ensure that they do not.

The objective of this entry is to provide a background and history of the debate and to outline some key issues arising within it. There are several aspects of this debate and in what follows they are discussed under three headings. First there is a brief historical sketch of the *nothing works* or *what works* debate. Next, there is a review of the

current position in relation to the evidence that can be used to answer questions of *what works*. Finally, this entry looks at the impact the debate appears to have had on trends in practices and policies in criminal justice.

Historical Sketch

As G. G. Gaes remarked in 1998, from the inception of the modern penitentiary in Western Europe and North America at the turn of the 18th and 19th centuries, until approximately the last quarter of the 20th century, there was a prevailing assumption within criminal justice that those who broke the law could change for the better. This was originally couched in notions of reform and redemption rooted in religious beliefs; a fundamental principle underlying the concept of the penitentiary was that of moral instruction and *correction* of character defects. In the 20th century alongside many other secular changes, a clearer understanding of patterns of crime emerged from criminological research and of human development from psychological and social research. This knowledge produced a growing recognition of the importance of structural, social, and familial factors in generating crime. Over successive decades, approaches to criminological research gradually adopted a more scientific perspective. For example, whether or not the sentences imposed by criminal courts achieved their intended effects came to be seen as an empirical question.

Context of the Debate

By the late 1960s, there were numerous pieces of research of this kind, creating what was then a novel situation. By collecting and scrutinizing the findings, it would be possible to investigate whether any conclusions could be drawn about methods of intervention that *worked*. Such investigations focused primarily, and sometimes solely, on the question of how to reduce reoffending. In the United States, the government of New York State commissioned a report on the effectiveness of rehabilitation with offenders. Work on this began in 1968, but it was not until the mid-1970s that the final version of the report, *The Effectiveness of Correctional Treatment: A Survey of Treatment Evaluation Studies*, was published,

incorporating the findings of 231 studies published between 1945 and 1967. Publication of the final project report was delayed while the results were scrutinized by a specially appointed panel of the National Academy of Sciences. Also in the mid-1970s, the United Kingdom's Home Office launched a project with some overlapping aims, although this had a slightly different main objective, to assemble and compare the outcomes of 100 studies on the effectiveness of sentencing (see Brody, 1976).

The authors of both of these reports found that many of the research studies done in this area were methodologically weak. The poor quality of research made the drawing of clear conclusions difficult. In advance of the publication of the New York State report, a member of the research team, Robert Martinson, published an article that provided what in due course transpired to be a somewhat inaccurate summary of the project's findings. That 1974 article, "What works? Questions and Answers About Prison Reform," is the origin of the phrase *what works* in this context. Martinson (1974) offered the disappointing conclusion that "education at its best, or psychotherapy at its best, cannot overcome, or even appreciably reduce, the powerful tendency for offenders to continue in criminal behavior" and that the findings "give us very little reason to hope that we have in fact found a sure way of reducing recidivism through rehabilitation" (p. 49). This announcement regarding the failure of rehabilitation—sometimes captured in an alternative phrase, *treatment is dead*—is widely regarded as having had a dramatic impact on penology from that point onward in English-speaking countries. While the article itself did not make the stark and literal claim that absolutely *nothing* worked, from accounts given by those involved at that time Martinson attained some celebrity status on the basis of it, and during a number of media interviews and public lectures was vehemently dismissive of efforts at rehabilitation.

In 1998, Gaes's publication of Martinson's article has been depicted as "a watershed event. In many ways, it ended a 150-year-old era of optimism about the possibilities of reforming the offender" (p. 713). S. Adams described it as having "shaken the community of criminal justice to its root" (cited in Cullen, 2005, p. 6). Over ensuing

years, its conclusions were challenged by a number of researchers. In 1975, Ted Palmer reanalyzed the data set used by Martinson and showed that almost half of the studies he cited had actually found positive effects. As a result of the way studies had been grouped together, with average effects calculated for each group, positive results within them had been overlooked. An article by Paul Gendreau and Robert Ross, published in 1987, collated a series of studies showing positive outcomes of offender treatment. Moreover, and somewhat ironically, in 1979, Martinson himself reanalyzed some of the data on which he had earlier worked, leading him to recant his initial negative conclusions: "I have often said that treatment added to the networks of criminal justice is 'impotent,' and I withdraw this characterization" (p. 254). He offered instead the more soundly based position that some interventions were beneficial, others not, while some were frankly harmful.

Despite these rebuttals and countervailing evidence, in a sense the damage was done. Over subsequent years, the legislatures of several U.S. states passed laws authorizing more severe penalties for offenders, removing educational and therapeutic services, and introducing other changes such as enabling the transfer of juveniles to adult correctional facilities. The ethos became one based almost entirely on the philosophy of punishment. In due course, the U.S. prison population began to rise steeply, reaching previously unheard-of levels: By 30 years later, it had expanded 7-fold. The extent to which the increasing resort to more punitive sentencing can be ascribed to the impact of Martinson's 1974 article, or was a trend that would have occurred in any case, is difficult to discern. A 1976 report of the U.S. Committee for the Study of Incarceration was also dismissive of treatment and advocated a penal policy based on just deserts and deterrence, and it too may have been influential. But that report also strongly advised that stringent limitations be placed on the use of imprisonment, which Martinson too had said did not work.

Thus, the emphasis given to the *nothing works* message was both simplistic and selective. Given the high political profile of the issues of crime, punishment, and rehabilitation, there are numerous agendas at stake when discussing the value of

research. Several writers on the subject suggest that for those who took a conservative stand on penal policy, including leading figures of the period such as Ernest van den Haag and James Q. Wilson, the finding that rehabilitation had failed was a message they had been waiting for. Hence the powerful sound bite *nothing works* may have resonated with other tendencies toward a widely felt need for a more punitive response to crime and came to be reflected in the decisions of many legislators and sentencers. By comparison, the message that prison failed received much less attention—indeed, it was essentially ignored, suggesting the move to mass incarceration was triggered, rather than fundamentally caused, by the reviews.

The Challenge to *Nothing Works*: Research Review and Synthesis

Throughout the era that followed, and despite the swing of the metaphorical law-and-order pendulum toward greater use of punishment, research continued on the effectiveness of interventions designed to influence and reduce criminal recidivism. By the mid-1980s, a new method of statistically synthesizing research had been devised, based on work in the evaluation of educational programs and of the effectiveness of psychological therapies in the field of mental health.

The advent of *meta-analysis* has had a far-reaching effect on many disciplines, and criminal justice is no exception. In asking *what works?* meta-analysis is a powerful tool for integrating the findings from separate research studies, taking account of differences between them, including variations in design and quality. The first review study employing this method to evaluate the effectiveness of offender rehabilitation was published in 1985, and by 2012, over 100 such reviews had been produced. Several more have appeared since then. These reviews have enabled researchers, and also practitioners and policy makers, to recognize and accept that while there are certainly approaches that do not work, and some that are downright harmful, there are others who achieve the desired effect of reducing criminal recidivism. It is simply not and never was the case that nothing works. These reviews have also made it possible to discern more clearly some of the features that

contribute toward making interventions more effective in the criminal justice system. Patterns within this have been mapped and conceptualized in what has become known as the Risk-Need-Responsivity (RNR) model.

Since its inception, the Risk-Need-Responsivity model has had a steadily mounting influence on correctional professionals and systems in many countries. It proposes that interventions are more likely to succeed in lowering criminal recidivism and promoting rehabilitation if they take three principal factors into account. The first is each individual's *risk level*: Assessing risk level is regarded as a core practice to evaluate the likelihood of future reconviction and allocate offenders to different levels of services accordingly. Doing so is usually based on information about an individual's criminal past (e.g., age when first convicted, number of convictions to date). The most intensive types of intervention are then reserved for those persons assessed as posing the highest risk. A substantial amount of evidence illustrates the value of doing this.

The second factor is risk-related variables or *criminogenic needs*: Research on persistent offending suggests that certain patterns of social interaction, egocentric attitudes, low self-control, poor social or cognitive skills, and other variables are recurrently associated with its emergence and maintenance. If work with offenders is to reduce their prospects of reoffending, those same variables should be its outcome targets. Such dynamic risk-need factors are then prioritized as objectives in rehabilitation services.

The third factor is *responsivity*: Certain methods or approaches have a superior record in engaging, motivating, and helping participants in criminal justice interventions to change. Rehabilitative efforts work better if they have clear, concrete objectives, if their contents are structured, and if there is a focus on activity and the acquisition of skills. Personnel involved in providing such rehabilitative efforts should possess high-quality interpersonal abilities and try to foster supportive, collaborative relationships within clearly defined boundaries. In addition, it is vital that intervention strategies be adapted to accommodate diversity among participants with respect to gender, age, ethnicity, sexuality, language, learning styles, and other individual differences.

Numerous books are now available illustrating the substantial volume of findings that have accumulated on the effectiveness of offender treatment (e.g., Craig, Dixon, & Gannon, 2013; Dvoskin, Skeem, Novaco, & Douglas, 2012; McGuire, 1995, 2002).

A parallel output from the amassed research, examined alongside databases of criminal statistics, may seem a paradoxical finding to many people. It is one that calls into question what may be thought of as obvious and indeed regarded as common sense. Considerable quantities of evidence suggest that the centerpiece of most criminal justice, the use of punitive sanctions, is in fact one of the least effective means of changing offenders' behavior. Society may employ punishment on the basis of its role as retribution: that having caused harm to society an individual must then suffer a disadvantage in return.

When researchers have examined approaches to sentencing that claim to be *consequentialist* in that they lend themselves to being judged by their effects, on balance they have found that punitive measures either have no effects or even adverse ones. While punishment can be an effective method of behavior change, to work well it needs to be applied with a high level of certainty, with speed and severity, and to activities for which there are alternative, law-abiding methods of achieving the same goal. In the complex real-world landscape of crime and justice, it is extremely difficult, if not impossible, for this combination of parameters to be administered.

Impact on Policy and Practice

As noted earlier, the initial and in many places enduring effect of the promulgation of the *nothing works* doctrine was a shift toward harsher sentencing practices. That probably occurred most spectacularly in the United States, but a similar trend was seen in the United Kingdom, where the demise of rehabilitation also afforded greater prominence to retribution and deterrence. Subsequently, however, as the evidence of positive effects of treatment began to multiply, many justice departments sought to reintroduce rehabilitation programs into penal settings. The largest scale departure in this respect was the Crime Reduction Programme instigated in England and Wales from

2000 onward. This program entailed the design, delivery, and dissemination of structured *offending behavior* programs at many prison and probation sites, supported by extensive investment in staff training. Evaluations of the program have shown significant drops in rates of reconviction among those who completed the programs, as compared with their predicted rates. However, these initiatives were not accompanied by a fall in the use of imprisonment, which has remained at historically high levels throughout the implementation period.

More recently, a more broadly based concept of evidence-based criminal justice, examining the wider impact of policies that draw on sanctions alone as a core principle, has emerged. The human cost of mass incarceration reaches beyond individual offenders, to their families, which experience damaging consequences as a result of it. That includes the next generation likely to be at risk of following criminal pathways, further amplifying its counterproductive impact. Furthermore, given that the strongest wish of most crime victims is not to be victimized again, the failure of punitive sanctions represents a poor service to them. Finally, the monetary cost of a policy deploying high levels of custodial sentencing is prohibitive, such that some legislatures have now placed limits on its use or have attempted to put the cycle of escalating prison numbers into reverse. These actions have led to moves in a number of jurisdictions toward *justice reinvestment*, a radical reappraisal of priorities and principles concerning how criminal justice systems operate.

As noted by the distinguished American criminologist Francis T. Cullen, psychologists have played a large part both in producing the research that has demonstrated the viability of rehabilitation and in formulating how that can be translated into practice. Of the 12 scholars whom he identified as having *saved rehabilitation* from the *nothing works* onslaught, 8 were psychologists. This illustrates the contribution the profession has made and can continue to make to this field and to the public.

NUESTRA FAMILIA

This entry examines Nuestra Familia, a major Latino prison gang in the United States and one of the earliest of such groups to develop in California. Prison gangs vary widely in their characteristics, but they form and operate in the penitentiary system, usually along racial or ethnic lines; maintain a vertical chain of command; obey a code of conduct; and require a lifetime membership. Inmates create these groups for reasons of self-protection in a hostile environment and commit or order crimes for their own economic support. From behind bars, prison gangs even direct street gangs to enforce their orders, perpetrate crimes on their behalf, and deposit their profits in return for protection during their own jail time.

In the United States, prison gang affiliation has steadily increased since the 1950s, but the paucity of official documentation, the secrecy of these groups, and limited external access to these groups mean that little research-based data are available on the nature and reach of prison gangs. These groups formed and gradually spread throughout the U.S. prison system as inmate populations grew larger, younger, more ethnically/racially mixed, and more violent. This entry considers the purpose, evolution, and nature of Nuestra Familia, reasoning that the organization adapted its structure to curtail internal corruption and has proved resistant to law enforcement efforts.

Origins and Development

Nuestra Familia arose in response to aggressions by the Mexican Mafia, today a leading prison

gang that formed in the Deuel Vocational Institution at Tracy, CA, in 1957. Los Angeles-based Chicanos had created the Mexican Mafia to defend themselves against other inmates but soon started abusing and extorting nonaffiliated Latinos, including Mexican American farmworkers from Northern California's agricultural Central Valley. Nuestra Familia laid its groundwork in Soledad State Prison but was formally born in San Quentin State Prison in 1968 when a Mexican Mafia member stole the shoes of a nonassociated Chicano who was stabbed to death when confronting the thief. This episode, known as the *shoe war*, boosted Nuestra Familia's membership and led to the establishment of its headquarters in Pelican Bay State Prison at Crescent City, near the California–Oregon border.

In 1973, the group commenced operations in the streets as members on parole were tasked with setting up street regiments. These crews were required to generate funds for incarcerated members, weapons purchases, and the drug business. With Bakersfield dividing the territories of the Mexican Mafia and Nuestra Familia, the latter extended its influence over the West's agricultural towns, notably Salinas, and detention facilities in other parts of the United States.

Affiliation with Nuestra Familia is symbolically expressed through the color red, the number 14 (which stands for Norteño or Northern California), and tattoos that may show a sombrero with a blood-dripping dagger or denote the various career stages in the group.

Vision and Objectives

Nuestra Familia aims to be a strong and self-supporting organization that works for the betterment of its members and enables them to retain their cultural identity as Chicanos. Its best interests go before everything else, including the individuals' own families and any material pursuits. The use of violence is meant to be restricted to ensuring physical protection from other inmates or to intervening in human rights violations committed in the penitentiary system. Nuestra Familia pledges to assist its incarcerated members by providing them with financial aid and discounted prison store goods, legal counsel, and emotional support. To accomplish these goals, it relies on

relatives and other collaborators outside of the prison who will act as couriers of messages and contraband, deposit funds, and facilitate unlawful activities. Crimes typically include murder, robbery, assault, witness intimidation, drug sales and distribution, extortion, and taxation of illicit income. Nuestra Familia began to stray from its original vision and abandon its members, particularly those sent to death row, when greed and corruption set in.

By 1978, the organization had been operating successfully enough to be earning tens of thousands of dollars of illegal revenue. Robert Sosa, at the time Nuestra Familia's General (or supreme commander), was mandated to administer these resources to further collective interests but had in fact embezzled more than US\$100,000 from the group's accounts. Sosa was impeached and Nuestra Familia's structure altered to impede future misconduct. In the mid- to late 1990s, however, a renewed decline in membership occurred when leaders turned to prioritizing drug profits over the protection of jailed Norteños. As of 2018, the Mexican Mafia, which controls Sureño street gangs operating in Southern California, remains Nuestra Familia's chief rival. Federal investigations indicate that Nuestra Familia has cooperated with Mexican drug trafficking organizations in distributing drugs and collecting drug proceeds in California.

Structure and Norms

Nuestra Familia's constitution, drafted in the 1970s and revised in the 1990s, sets out the organization's structure and the code of conduct to which members are expected to adhere. The document specifies responsibilities, including individuals' obligation to help establish street regiments or territorial units; decrees mandatory lifetime membership as well as the automatic expulsion of traitors; explains misconduct, including drug consumption; and stipulates the corresponding sanctions and complaints procedures.

Nuestra Familia is structured along quasi-military lines to enforce these rules and ensure the organization's smooth running. Initially, the top layer of the hierarchy comprised a general who wielded absolute authority but could be impeached if he was found not to work in the organization's best interests. This person oversaw

10 captains (or regimental commanders), who managed operations in their respective prison and directed regiments comprising numerous lieutenants and soldiers. In turn, the lieutenants schooled recruits, ensured basic needs were met, monitored conduct, and administered discipline when ordered.

When the original system of checks and balances proved unable to prevent the abuse of power for personal gain, a three-member organizational governing body was created in the early 1980s. Replacing the top general was *La Mesa* (The Table), whose members were elected and took decisions by two-thirds majority of votes. A new three-category system was introduced to grade members by rank and experience, ranging from recruits to educators and managers. From this third category, individuals were chosen for positions with voting rights in the organizational governing body, such as the General Council, the Inner Council, and the Generals.

In 1984, however, Nuestra Familia also created Nuestra Raza in Folsom State Prison with the objective of spreading its vision in mainline prison and repelling outside threats. Specifically, Nuestra Raza members were asked to unite Norteño street gangs so as to better defend turf and drug markets against Sureño gangs that in the early to mid-1990s sought to expand the Mexican Mafia's influence in Northern California. Nuestra Raza comprises selected Norteño gang members that follow Nuestra Familia's orders and are potential recruits for the organization. Norteño gangs pay taxes to Nuestra Familia, but once behind bars, they are trained in the group's history, philosophy, and strategy. Those who pass the requisite tests can move into Nuestra Raza.

Nuestra Familia's grip over these two auxiliary groups weakened when the drug business progressively displaced more altruistic concerns. Infighting occurred and intensified when some favored a truce with the Mexican Mafia and others rejected it so the organization could strengthen its power both inside and outside the correctional system. As members of Nuestra Raza and the Norteño gangs began rebelling against the dictates of an entity that had lost its way, Nuestra Familia turned to dealing more aggressively with dissenters in its ranks.

Recruitment and Membership

Unless they have relatives in the organization, individuals can only join Nuestra Familia if they are backed by one of its current members. The sponsor is held accountable for the recruit who must learn about the gang's history and constitution as well as literacy and survival skills. Membership is approved when the apprentice demonstrates the necessary knowledge and moral standing. Murder is not a criterion of admission but of promotion to more senior positions.

The Federal Bureau of Investigation's 2011 National Gang Threat Assessment reported the existence of 33,000 gangs with approximately 1.4 million members in the United States. Prison gangs constituted 16% of the total gang population but declined to 9.5% by the time of the 2013 report. According to law enforcement estimates, Nuestra Familia has some 400–600 incarcerated members and about 1,000 associates who work for the organization without formally belonging. These numbers, however, do not convey the destructive impact not only on members themselves but also on local communities affected by the violence.

Prison and Law Enforcement Interventions

In an attempt to reduce the membership in prison gangs and to eventually dismantle them, the United States has mostly adopted a suppressive approach. Correctional facilities long sought to break up various groups by scattering their members to various institutions, but this strategy effectively spread gang activity throughout the state and federal prison systems. Since the 1990s, authorities have separated gang members from the general inmate population and have isolated their leaders in order to interrupt their communications and decrease violence. Research suggests that segregation helps reduce conflicts but does not succeed in curbing interactions, let alone eradicating prison gangs. Indeed, this policy may inadvertently reinforce gang identities and bolster gang cohesion.

Law enforcement authorities have made use of inmate informants and assertively prosecuted the crimes committed by prison gang members. Operation Black Widow, launched in 1997, was an

extensive 7-year federal effort to investigate and prosecute senior Nuestra Familia leaders. Although the actions constituted a severe blow to the organization, those convicted received light sentences in negotiated plea deals and took their gang activity to prisons outside California. Operation Black Widow was followed by a series of other operations aimed at removing the leaders on the streets. However, Nuestra Familia proved resilient. By adapting its communications system, eliminating perceived snitches, and employing violence with greater discretion, it even managed to expand its flourishing drug business.

The enduring strength of Nuestra Familia, and its unbroken influence over Nuestra Raza and Norteño street gangs, shows that the combination of identity, solidarity, respect, fast money, and power retains its allure for many socially excluded individuals. Tackling prison and street gangs more effectively will require more than prosecuting and incarcerating those who have broken the law. While it is imperative to make prison management and rehabilitation more effective, reducing the pernicious consequences of gangs will require greater community development, better counseling services, and a greater number of dignified education and job opportunities. In the meantime, further research would update and improve the

understanding of the nature and workings of prison gangs, as well as their relationship to street gangs in different contexts.

OCCUPATIONAL AND CORPORATE CRIME

Occupational crimes and corporate crimes are generally considered prominent forms of white-collar crime. Although terms such as *white-collar crime*, *occupational crime*, and *corporate crime* are often used interchangeably, it is important to identify distinctions among these different crimes. *Occupational crimes* refer to crimes perpetrated during the course of a person's legitimate occupation by leveraging access within an organization and/or status as a trusted professional for personal gain, often at the expense of the organization itself. Occupational crime can be committed by anyone in an organization ranging from lower level employees stealing money or supplies to executives embezzling money for personal gain. In contrast to occupational crimes that focus primarily on individuals, *corporate crimes* refer to crimes committed by a company through the collective harmful actions of many individuals throughout an organization who make conscious decisions to engage in crimes to further either their own goals or those of the organization. Generally, corporate crime consists of socially harmful actions taken on behalf of the corporation, presumably to further the organization's interests but which ultimately may cause tremendous harm not only to society at large but also to the organization itself. An important distinction is also appropriate between occupational and corporate crime and other types of deviance (violations of behavioral norms)

occurring in occupational settings (e.g., sexual harassment and alcohol or illicit drug use). These actions may or may not constitute criminal offenses, but they are considered inappropriate in the workplace. Similarly, other conventional street crimes (e.g., homicide, assault, vandalism) can occur in the workplace but are not considered occupational or corporate crimes. This entry provides an overview of the impacts, characteristics, and motivations of occupational and corporate crimes, then examines the types of occupational and corporate crime that are most common.

Impacts

Occupational and corporate crimes result in substantial societal harm ranging from individual monetary losses to adverse macroeconomic, human health and safety, and environmental impacts. Due to their complexities and the substantial *dark figure of crime* (where only a small portion of crime becomes known to law enforcement and thus reflected in official records), the scope and scale of the damages to consumers, employees, businesses, investors, and society from occupational and corporate crime is impossible to fully measure. Undoubtedly, the total impact of these crimes is more widespread than what is known.

Occupational and corporate crimes take many forms and have been persistent throughout history. Many early corporate crimes centered on trade manipulation by restricting access to food and supplies for economic or political gain. One

case that shaped contemporary ideas of corporate crime was the South Sea Company Bubble in London in the early 1700s, whereby the company's stock price was artificially inflated through excessive speculation over the course of a decade, eventually leading to its collapse and massive losses. The crime was facilitated by insider trading and corruption through bribery of politicians and other officials. In the United States, some of the most egregious corporate crimes have included the railroad scandals of the mid-1800s, bank collapses in the 1920s and 1930s (contributing to the onset of the Great Depression), the savings and loan crisis in the 1980s, large-scale corporate frauds of the early 2000s (e.g., Enron, WorldCom, Tyco, Global Crossing, Adelphia), and the subprime mortgage crisis in the late 2000s, which nearly led to the collapse of the global financial system. These crimes resulted in various regulatory reforms of the legal structure dictating corporate governance and criminal liability.

Characteristics

Occupational and corporate crimes exhibit several notable characteristics. Occupational and corporate crimes rely on a false sense of legitimacy, restricting the ability to detect them, particularly in the short term. This false legitimacy requires the use of deception. Offenders often disguise their true intentions and maintain an upstanding, professional outward persona to gain seemingly legitimate access to potential victims. These victims are often employers, employees, investors, customers, vendors, or others who regularly associate with the offenders. Interactions tend to occur during routine, day-to-day activities that fail to arouse suspicions.

In addition to legitimate access, occupational and corporate crimes involve deliberate and calculating attempts to conceal the crime, both during its commission and after it is uncovered. Elaborate concealment techniques coupled with the legitimate appearance of the offense make detection especially difficult. Technological advances, including the widespread use of electronic transactions, have made it easier for offenders to engage in crime virtually, maintaining substantial distance from their victims. Detecting *cyber* crimes can be particularly challenging as concealment may

involve layers of complex transactions and the collusion of multiple parties.

Another distinctive characteristic of occupational and corporate crime is an abuse of trust in the offender–victim relationship. It is impossible to navigate the intricacies of modern society without the ability to trust professionals to care for various aspects of life. For example, doctors are relied upon to diagnose and treat illnesses; banks, investor–brokers, or financial advisers to manage and protect money; lawyers to provide sound legal advice; and auto mechanics to properly repair vehicles. These trust-based relationships stem from knowledge or information asymmetry, where experts in various professions maintain an advantage over those whose expertise lies in other areas. This trust is therefore necessary for society to thrive, while simultaneously generating perpetual opportunities for abuse when personal interest conflicts with a professional's fiduciary responsibility.

Finally, occupational and corporate crimes are difficult to detect, prevent, and sanction and have not received as much attention as conventional street crimes. Although originally meant to bring attention to the crimes of powerful individuals of higher social status who were not receiving adequate attention in the criminal justice system, many have adopted an offense-based approach to white-collar crime, focusing on the specific type of crime as opposed to the socioeconomic status of the offender. While these offenders sometimes have high socioeconomic status, most convicted offenders are not powerful elites but instead are middle-class individuals involved in more mundane crimes. Corporate crime offenders found in official records are not necessarily well-known multinational corporations but are more typically small- to medium-sized businesses. One reason for this is that there are more smaller businesses than larger corporations, making it more likely that their criminal activities will be identified and represented in official records. Another is the power differential between large and small businesses, where large corporations use their influence to avoid criminalization of their harmful actions.

Motivations and Rationalizations

Humans are driven by the desire not only to better their lives but also to be socially accepted and

viewed as successes in the eyes of their peers. Similarly, since the dawn of the corporate organization, there has been a drive to gain and maintain strategic advantage to survive and thrive in a competitive environment. These pressures are a tremendous incentive to bend or break the rules, regardless of the negative impacts on others. Occupational and corporate criminals are not always greedy one-time offenders but consist of intermittent opportunists as well as chronic repeat offenders. While economic gain is often the primary motivating force behind these crimes, many motivations can compel professionals to act unlawfully. For instance, what is commonly perceived as greed-based behavior could also be interpreted as the fear of failing to meet expectations or maintain the status quo and/or social status. Various other forces influence criminal behavior, including personal emergencies, interpersonal conflicts, and changing external environments.

In addition to individual motivations, organizational characteristics (e.g., history, structure, processes, and culture) motivate and/or encourage rationalizations legitimizing criminal behavior. Organizational history includes the development and changes to the organization over time, including types and numbers of workers, leadership, and significant events influencing where an organization has been and what its future in relation to the rest of the world will be. In addition to history, corporations have varying structures, ranging from pyramidal and centralized to flat and decentralized. Depending on the specific structure, allocation of authority, and channels of communication throughout the organization, there may be greater or fewer opportunities and incentives for crime.

Organizational culture is highly complex with both internal and external pressures interpreted differently by individuals throughout the organization. An organization's profit-oriented culture is one of these crime-conducive characteristics. As organizations are primarily evaluated by how efficiently and effectively they achieve their economic goals, considerable pressure is placed on employees to meet high expectations with regard to profitability, market share, brand recognition, and financial capital. Culture is generally dependent on the tone set at the top of the organization.

Management decisions and policies prescribe organizational goals and dictate the acceptable means to achieve them. Employees can be socialized into conformity through patterned interactions with one another, which can result in an increased likelihood of *groupthink*, or lack of individual discernment. Many come to the belief that preserving the organization's reputation, maintaining market share, preventing investor losses, or advancing their career is more important than other priorities, including adhering to the law. This is not to say that executives and managers are explicitly promoting criminal behaviors, but inaction or indifference is sometimes sufficient to propagate a deviant organizational culture. Cultural transmission, thereby, plays a role in pulling individuals toward a mental state where certain departures from conventional societal norms are accepted to achieve organizational goals.

Various justifications and excuses are used to neutralize the potential impacts of occupational and corporate crimes. One of the most common rationalizations is the denial of responsibility, whereby offenders deny culpability for their actions and shift blame elsewhere. This is easy to accomplish in the context of an organization where multiple actors are involved and a scapegoat is readily identifiable. It is common for offenders to diffuse the harm resulting from their crimes across numerous victims by arguing that each individual victim experienced little or no actual damage. This is common when the crimes victimize many investors or employees or when taxpayers are the primary victims. Taken together with limited direct contact and the difficulty in identifying victims, offenders can often neutralize any guilt for their actions.

External influences further impact rationalizations for occupational and corporate crimes. The complexity of laws and regulations often results in frustration and apathy, with many perceiving the law as illegitimate or unreasonably inhibiting their ability to succeed in a free market economy. Similarly, they may perceive law enforcement as incompetent and untrustworthy, condemning those who are accusing them of wrongdoing. Frequent regulatory changes in certain industries can also serve as an excuse for crime due to unfamiliarity with new rules.

These characteristics of corporate organizations influence offenders' rationalization processes, which in turn allow them to reinterpret their situation as exceptions to their underlying moral beliefs, thus justifying their criminal behavior. Furthermore, given the difficulties in detecting and prosecuting occupational and corporate crimes (especially in terms of establishing motivation and intention), these organizational characteristics represent frequently used (and often successful) strategies for avoiding criminal liability for occupational and corporate crime.

Common Offense Types

Occupational and corporate crime take numerous forms including embezzlement; bribery and corruption; economic espionage; fraud (e.g., securities fraud); insider trading; tax avoidance; antitrust violations; and health, safety, and environmental violations. This should not be considered an exhaustive list but instead an illustration of several common types of occupational and corporate crime.

Embezzlement

Embezzlement is the misappropriation of money and/or personal properties belonging to an organization by offenders who leverage positions of trust to perpetrate the theft, such as when an executive siphons money from a company for their personal use.

Bribery and Corruption

Bribery (e.g., kickbacks) typically involves two or more parties in a quid pro quo relationship, where one party offers something of benefit (often money) in exchange for a specific outcome, such as a business deal, favorable treatment, or a change in the law or other rules.

Economic Espionage

Espionage refers to the theft or misappropriation of intellectual property, typically by selling it to a foreign government or competing organization. While traditionally thought to mainly impact technology companies (particularly those with defense contracts), any industry can be affected.

Theft of proprietary products, trademarks, and manufacturing processes are increasingly prevalent, as evidenced by widespread cases of product counterfeiting.

Fraud

Fraud is an all-encompassing umbrella term used for various illegal activities involving the use of deception and/or concealment to misrepresent information to achieve some type of illicit gain. Such deception can vary in scale and across various industries. For example, securities fraud (i.e., stock or investment fraud) involves the misrepresentation of commodities or stocks to entice investors. Many high-profile corporate crimes have involved fraudulent financial statements (e.g., Enron, WorldCom, Freddie Mac, Lehman Brothers).

Insider Trading

Insider trading represents a breach of fiduciary responsibility by individuals with special access to information that is either confidential or has not yet been publicized. These offenders take advantage of their privileged knowledge by trading the company's securities at strategic times for personal financial gain.

Tax Avoidance

Tax avoidance is the deliberate underpayment or nonpayment of taxes owed to governmental entities. This can include the use of tax shelters, although the complexity of tax codes often provides these methods the appearance of legality. Failure to report income gained through illegitimate means (e.g., committing other crimes, such as drug trafficking) is also considered tax avoidance.

Antitrust Violations

Antitrust violations refer to the creation of monopolies that interfere with legitimate market competition. Examples of anticompetitive conduct may include exclusive dealing arrangements, mergers and acquisitions designed to monopolize market share, and price discrimination.

Health, Safety, and Environmental Violations

Corporations are subject to laws and regulations designed to protect the public interest, human health and safety, financial stability, and consumer and environmental protection. Crimes are often committed by companies violating the letter and/or spirit of these laws.

OCCUPATIONAL CRIME: PREVALENCE AND STATISTICS

Occupational crime involves violations committed by an individual through opportunities that arise in the course of a legally defined occupation. This entry provides an overview of the nature of occupational crime and examines the prevalence and types of such crimes committed by employees acting against the interests of organizations, including business corporations, nonprofit organizations, and government agencies.

Inventory Shrink

Since the 1990s, the National Retail Federation has conducted an annual survey of leading businesses

in an array of retail sectors to assess the incidence of internal and external retail crime. *Inventory shrink* is the term given to the loss of merchandise in a retail organization. According to the figures gathered by the National Retail Federation, shrink as a percentage of sales amounted to 1.38%, producing US\$44 billion in losses for U.S. retailers in 2014 and US\$45.2 billion dollars in losses in 2015.

Shrinkage losses in the United States varied by market sector. The grocery industry has long suffered from high levels of shrink, and that trend appears to be increasing, with a 3.6% rate in 2015. Specialty men's and women's apparel was slightly below the overall average at 1.2% of sales. Discount, mass merchandise, and super center retailers were slightly below average, with 1.1%, but 60% of respondents in this category reported that 2015 brought an increase, compared to 48% overall who saw an increase. The sources of inventory shrink can be divided into five categories:

- employee/internal theft (35.8%)
- shoplifting, including organized criminal collusion (39.3%)
- administrative and paperwork errors (16.8%)
- vendor fraud or error (4.8%)
- unknown loss (7.2%)

Counterproductive Employees

Historically, employee theft has been the greatest cause of inventory shrink. Other sources appear to be on the rise, but employees are still responsible for more than US\$16 billion in U.S. retail losses. In 2013, it was estimated that global losses due to employee theft totaled about US\$3.7 trillion. For some sectors where additional information is available, such as the grocery sector, long-term data demonstrate that the challenge of counterproductive employees remains acute. It is also metastasizing into dangerous new forms of criminal activity, indicating the need for vigilance in hiring and supervision.

Employee Criminal Collusion

In one form of theft known as *sweethearting*, employees may illicitly circumvent established procedures or systems to benefit relatives and friends. This conduct includes avoiding the bar

code scanner for merchandise, overriding printed prices at the cash register, or simply not invoicing goods and services (especially in the restaurant, hospitality, and home installation industries). In a small, nonrandom sample, 67% of respondents said they had participated in sweethearting in the past 2 months. Many employees surveyed said they were motivated by the prospect of receiving better tips and similar reciprocal deals at the customer's place of business.

In more sinister collusion, employees use their inside knowledge of security protocols to aid teams of professional shoplifters, burglars, or cargo hijackers. They also may cooperate with gift card, barcode, or receipt fraud artists who may be independent actors or part of street gangs or related criminal organizations. A National Retail Federation survey of businesses indicated this is a growing problem, with slightly more than 20% of employee-theft cases investigated involving collusion with an outsider, including in some sensitive, high-security environments. For example, over 22% of suspects in a large multiairport theft operation in Canada were current employees.

The Employee Organized Retail Crime Risk Triangle introduced by Michael Cunningham and John Jones emphasizes three major contributors to such collusion:

- *Organized Retail Crime Pressure* is an influence from organized criminals that increases the employee's feeling of financial need, stress, or coercion.
- *Collusion Opportunity* involves establishing the initial relationship between the external criminal and the internal employee and then actively engaging in joint criminal cooperation.
- *Organized Retail Crime Tolerant Attitudes* allow employees to justify the theft in their own minds and then minimize the risks associated with stealing.

Embezzlement and Fraud

Embezzlement is a type of financial fraud involving the covert diversion of an organization's or individual's assets for personal use. Embezzlement can involve the use of fraudulent invoices and bills for service to cover illicit asset transfers, or it can involve skimming or diverting money before it is registered as income.

According to Federal Bureau of Investigation statistics, embezzlement has a lower incidence than other forms of fraud committed by independent criminal perpetrators (e.g., swindle/confidence games, credit card/ATM fraud, impersonation, wire fraud, and health and welfare fraud). Nonetheless, accounting and finance employees along with asset management and other loss prevention professionals who are in positions of trust often have access to substantial funds. As a consequence, losses due to embezzlement can range from thousands to millions of dollars.

Fraudulent billing for time, services, and expenses is another category of occupational crime. In one notable example, a partner in a major Chicago law firm claimed billable time, on average, for 5,941 hours per year for 4 years in a row, which amounts to 16 hours per day, every day, for 365 days. A survey of attorneys reported that 12.3% suspected that their colleagues pad their hours frequently, with reported losses ranging from the thousands to the millions of dollars. The majority of overbilling is neither detected nor prosecuted, so reliable prevalence data are unavailable.

Schemes against government and private health-care insurers are the most expensive forms of fraud. The National Health Care Anti-Fraud Association estimates that health-care fraud is about 3% of total health-care spending, costing the United States about \$68 billion annually. In fiscal year 2015, the Department of Justice opened 983 new criminal health-care fraud investigations, with federal prosecutors filing criminal charges in 463 cases involving 888 defendants. A total of 613 defendants were convicted of health-care fraud-related crimes during the year. Also in fiscal year 2015, the Department of Justice opened 808 new civil health-care fraud investigations and had 1,048 civil health-care fraud matters pending. Approximately US\$2.4 billion was returned to the federal government or paid to private persons as a result of such recovery efforts.

Cyber Crime and Cyber Negligence

The Internet age has allowed instantaneous purchases and transfers of information and money, increasing transactional efficiency but opening organizations up to a host of digital vulnerabilities. Organizational assets, including

money, intellectual property, and client personal information, are susceptible to threats from domestic and foreign criminal actors who try to hack their way into an organization's information technology system. Reliable prevalence statistics are unavailable because most companies choose not to disclose penetrations and losses if they can avoid it, but the Federal Bureau of Investigation's Cyber Division reports that billions of dollars and millions of pieces of personal identity information are lost every year due to cyber intrusions.

Individual employees may engage in embezzlement using digital systems, but the greatest internal financial threats to organizations stem from collusion. The Association of Certified Fraud Examiners estimated that 45% of losses involve insider collusion. Many employees are in position to collude with external criminals by offering inside information (e.g., system architecture, defenses, and passwords) or assisting with the installation of malware to facilitate cybercrimes. An employee's motivations to collude may include loyalty to acquaintances, or fear of them, personal financial gain, or support of drug habits.

An equally serious security problem confronting organizations is social engineering (i.e., the manipulation of an unwitting employee by criminals to release valuable information). This can be done through a phishing e-mail (i.e., an innocuous-appearing electronic message containing malware allowing the criminal to gain access to the employee's computer). A 2016 Verizon study noted that 13% of people tested clicked on a phishing attachment. Manipulation also can be conducted through text messages, e-mail, or phone calls in which the criminal purports to be a fellow employee or client who has forgotten a username, password, or the URL of an access point and simply needs assistance from the unsuspecting employee.

Whether a cyber criminal's goal is individual identity theft or to compromise the entire organization, the naive employee is the weak link. Verizon reported that 63% of confirmed data breaches involved leveraging weak/default/stolen passwords. Because of the importance of employees in protecting assets, employee selection and training for integrity and conscientiousness, along with a focus on security and safety, must be a crucial part

of an organization's defensive strategy. Employees must be taught that protecting their client's and their company's confidential information is a crucial aspect of excellent service.

Risk-Taking and Safety Violations

Most employee risk-taking and unsafe behavior occurs in settings considered private property, such as in warehouses and on factory floors. While costly to employers, such behavior is not categorized as criminal conduct. One notable exception involves logistics and transportation workers. While employee-specific statistics on a variety of dangerous moving violations (e.g., highway speeding, running red lights, violating railway crossing signals, failure to use seat belts, or the illegal use of cell phones or text messaging while driving) are not available, the prevalence of these risk behaviors is of paramount concern.

Research commissioned by the Federal Motor Carrier Safety Administration found that the odds of being involved in a safety-critical event (e.g., crash, near-crash, unintentional lane deviation) are 23.2 times greater for drivers who text while operating a commercial motor vehicle than for those who do not. Using a handheld mobile phone to call or text is illegal for commercial operators, even if it involves pressing just one button. Calling from a mobile device remains legal for commercial operators only if the device is completely hands-free. The impact of these regulations, and other safety programs, on the rate of large truck and bus crashes, injuries, and fatalities is not yet apparent.

Employee risk-taking and safety violations can also represent criminal conduct when pollution controls are overridden and unsafe products or conditions are created, endangering others. This would include the covert discharge of harmful chemical effluents into rivers and the use of banned ingredients in production, such as lead paint on toys. The prevalence of such violations is unknown, but the risks can generally be managed through proper training and employee adherence to proper safety procedures. Conversely, employees are more likely to take risks when they do not believe that there will be sanctions for their high-risk behavior or when they do not believe that their employers are committed to their safety policies.

Sabotage, Violence, and Harassment

Employee sabotage can occur in the form of criminal conduct, including setting deliberate fires, breaking equipment, or damaging goods, or in the form of counterproductive conduct, such as reduced personal effort or quality control, demoralization of coworkers, or hostile company commentaries posted anonymously online. Although research has been conducted on the antecedents and consequences of sabotage in both the manufacturing and service sectors, prevalence statistics are unavailable.

Employees are much more likely to be the victims of violence from external criminal threats than from fellow employees. Only 59 of the 1,063 workplace homicides in 1993, for example, were committed by coworkers. However, a study of coworker violence and incivility among nurses, including incidents involving physical aggression, revealed that unprofessional coworker behavior, disagreement over responsibilities for work tasks or methods of patient care, and dissatisfaction with a coworker's performance were frequently mentioned causes of conflict. Effective and equitable procedures for the resolution of workplace disputes may reduce such conflicts.

Workplace harassment is a form of criminal conduct that can include physical and emotional intimidation or bullying. In a 2015 study, approximately 10% of over 11,000 workers in a unionized government organization felt that they had been bullied during the prior 6 months, with 71.9% of those who reported regular bullying identifying the perpetrator as a supervisor or top management. In a survey of 1,016 human resource professionals, 22% reported incidents of pushing or shoving and 13% reported fistfights. Bullied and abused subordinates may be at risk of engaging in retaliatory violence against supervisors or sabotage against the organization.

One of the more prevalent forms of occupational crime is sexual harassment. In 1993, Louise F. Fitzgerald's pioneering work on this topic suggested that approximately one third of women had experienced sexual harassment in the workplace, including nearly 10% who had been directly pressured for sexual cooperation, and a comparable percentage who reported repeated unwelcome phone calls, notes, and letters. Sexual harassment statistics from other countries are even higher.

According to a 2017 United Nations report, 35% of women globally have experienced physical or sexual violence. In London in 2012, more than 40% of women had experienced sexual harassment in the street during the previous year. Research in 2015 by ActionAid in Brazil found 86% of women surveyed had been subjected to harassment or violence in public, which is comparable to South Africa where 80% of women surveyed had experienced some form of abuse in the past year. Based on sexual harassment scandals in 2017 involving U.S. politicians, entertainment, and media figures, this problem has not yet begun to abate.

Final Thoughts

The prevalence and diversity of counterproductive employee behavior highlights the need for reliable and valid preoccupational assessments, effective training, and evaluation programs, as well as continued monitoring of both employees and company metrics for signs of occupational crime.

OFFENDER GROUP RECONVICTION SCALE (OGRS)

The Offender Group Reconviction Scale (OGRS) is the name of a series of actuarial risk assessment instruments for use with convicted criminal offenders. Each version of OGRS has been developed for and used by the adult correctional services of England and Wales, directed since 2004 by the National Offender Management Service, which in 2017 became Her Majesty's Prison and Probation Service (HMPPS). Versions of OGRS have been used to predict general and sometimes more serious recidivism among probationers since 1996 and prisoners since 2009. OGRS scores are of considerable importance in court reporting as well as in allocation of offender services and research. Successive updates to OGRS have amended the measurement and scoring of its risk factors to improve its usability and validity as a predictor of reoffending, as well as to ensure that it reflects contemporary patterns of recidivism. This entry examines the application and scoring of the OGRS and provides an overview of its development.

Applying a Static Actuarial Risk Assessment Instrument

OGRS fulfills the demand for an actuarial risk assessment instrument with high levels of predictive validity (as confirmed by prevailing standards in forensic psychology), scored only from easily available static risk factors. Scoring each version of OGRS requires the offender's gender; dates of birth, conviction, and discharge from custody (when this sentence has been passed); current offense; and a small number of criminal history variables. The resultant scores are estimates of the probability of recidivism within 2 years of discharge from custody or sentencing to a noncustodial court disposal. At court, probation services include OGRS scores in presentence reports to the sentencing judge or magistrate. (Presentence report assessments always assume that a noncustodial sentence will be passed.) After sentencing, minimum OGRS scores form part of the criteria determining suitability for offending behavior programs, operationalizing the risk aspect of the

Risk-Need-Responsivity paradigm upon which HMPPS programs are based. OGRS score thresholds are also referred to when determining an individual's overall level of probation service and, in aggregate, when producing management information reports used in the commissioning of rehabilitative interventions and other offender services. OGRS scores are used by researchers to control for recidivism risk when evaluating interventions and have been used to compare outcomes between those receiving different sentences. They are also a key part of the Payments by Results contractual agreements between the Ministry of Justice and private probation providers, known as Community Rehabilitation Companies (CRC). These agreements specify that the CRCs will receive additional payments, known as Payments by Results, when cohorts of offenders have recidivism rates significantly lower than their OGRS baseline. The reoffending rate of each cohort is compared with that of the baseline 2011 cohort, and a comparison of OGRS4/G scores for the baseline and current cohort is used to adjust the current reoffending rate to reflect changes in the case mix of offenders being supervised.

The Development of the OGRS

Version 1 of the OGRS (OGRS1) was published in 1996. Its development involved several stages common to all versions. The criminal records of tens of thousands of offenders given sentences involving custody or probation management were traced on a central database to score risk factors and determine recidivism status within 2 years of community sentence or discharge from custody, weighting risk factors in a logistic regression model. At that time, the source database was the now defunct Offenders Index, which listed only the dates of convictions for relatively serious offenses. A key risk factor derived from these criminal histories is the *Copas rate*, named after a coauthor of OGRS1. An offender's Copas rate, and thus OGRS score, is higher when the offender has many criminal appearances and when the offender's criminal career (i.e., from first to current appearance) is short. Younger, male offenders and those with current offenses of burglary and theft also receive higher scores in all versions of OGRS.

Published in 1999, OGRS version 2 (OGRS2) was designed to be scored using personal computers rather than pocket calculators (which were used with the OGRS1) and involved a more complex set of risk factors. An additional scale, OGRS2-SV, estimated the combined risk of sexual and violent recidivism.

OGRS version 3 (OGRS3) was published in 2009, and it introduced several substantial technical and practical improvements. The Offenders Index was replaced with a research extract of Police National Computer data, which records a wider range of offenses and includes those resulting in formal cautions as well as convictions. As Police National Computer data include offense dates, the new recidivism outcome, *proven reoffending*, measures offenses committed (not convicted) within 2 years that eventually result in caution or conviction, while criminal history counts now include cautions. As further validation showed that the OGRS2-SV Scale failed to predict proven sexual reoffending, it was withdrawn and not replaced. The underlying algorithm was revised to model age separately for men and women, increasing predictive validity for female offenders. Efforts to lessen burdens on assessors led to a reduction in the number of data items required from nine to six, with trivial impact on predictive validity. OGRS3 was the first version implemented in prisons as well as probation, improving the integration of sentence plans for released offenders.

Published in 2015, OGRS version 4 (OGRS4) models reoffending over any given 2-year period, rather than only the first 2 years after sentence or discharge. The amount of offense-free time since sentence/discharge is therefore an additional scored factor. Development of an evidence-based classification of nonsexual violent offenses allowed the introduction of a violent reoffending predictor, OGRS4/V, with the general reoffending predictor now named OGRS4/G. Instruments combining static and dynamic risk factors, versions 2 of the OASys Violence Predictor and OASys General Reoffending Predictor, were developed using the same sample. Comparable violent and general recidivism predictions are therefore available for all offenders, with the slightly superior versions 2 of the OASys Violence

Predictor and OASys General Reoffending Predictor recommended in preference to OGRS4/V and OGRS4/G where possible.

Future Research

As of early 2018, OGRS3 is in use across HMPPS. OGRS4 is used to calculate Payments by Results and awaits operational implementation through upgrades to HMPPS case management software. Future developments being considered by HMPPS analysts include the use of alternate statistical methods (e.g., random forests) to estimate risk and the development of live links to the Police National Computer to score predictors automatically. Improvements to case management software should also facilitate more frequent updates to OGRS and other actuarial instruments, as complex code revision processes will be replaced by a dedicated risk-scoring software module.

OFFENDER RISK ASSESSMENT: CULTURE AND GENDER CONSIDERATIONS

The applicability of risk assessment tools to diverse offender populations is a relevant consideration for all criminal justice organizations. The primary benefit of structured risk assessment is that it enables the use of accumulated knowledge on risk factors to be reliably applied to individuals with accuracy, in order to predict future offending and, in turn, inform sentencing, custody security ratings, community release, supervision conditions, and treatment needs. However, one of the assumptions of standard risk assessments is that they apply equally to all offenders, even though they have primarily been developed on largely White male offenders. Therefore, their use with offenders of varied ethnic/racial, cultural backgrounds, and genders has been highly criticized. Some of the main considerations that fuel the conversation around the generalizability of risk assessment to varied genders and cultures include (a) the potential influence of cultural or gender bias, (b) inappropriate or inadequate measurement of current risk factors, and (c) lack of culturally relevant or gender-relevant risk factors. This entry discusses considerations related to the use of risk assessment tools with individuals from diverse cultures, including a case example, followed by a focus on how risk assessment tools are used with female offenders.

Culture

When assessments are applied to groups that differ significantly from the construction samples, they are criticized for making the assumption that the assessments, and the risk items comprising the assessment, are equally valid to the new group. This criticism has been raised largely by those questioning the validity of these tools with ethnic minority groups, predominantly those overrepresented in criminal justice systems, such as African American and Hispanic peoples in the United States and Indigenous peoples in Canada, Australia, and New Zealand. One of the main concerns with using risk assessments developed on one

group with different and diverse populations is the potential for cultural bias. This is particularly salient to issues pertaining to cross-cultural validity as well as minority groups who are overrepresented in many criminal justice systems around the world.

More specifically, the argument around cultural bias contends that generic risk tools ignore the unique historical and present context of many ethnic/racial groups that may be relevant to their offending trajectories. This is particularly relevant for ethnic/racial groups who have experienced the oppression of colonization, the vestiges of which in many cases persist today, through the social, political, and economic marginalization of these groups (see Case Example later in this entry). It is argued that the use of these assessments, founded on the cultural values and experiences largely representative of Western society, not only improperly capture risk, they also serve to further disadvantage the cultural minority (through consistently higher scores on risk tools) when used for legal and criminal justice decision-making (e.g., security classification, program allocation, release back into the community).

Similarly, given the potential differences in the underlying values across cultural groups, the adequacy of the risk factors being measured within these tools has been called into question. Additionally, the lack of culturally relevant *and* culturally specific risk factors has been identified by some scholars and practitioners as a shortcoming of risk assessment, as it is applied to such varied racial populations. For example, having a history of emotional problems and victimization has been shown in some research to be predictive of offending for Indigenous populations but not for non-Indigenous offenders. It could be that this factor is more relevant to the offending patterns of Indigenous peoples given their differential history of victimization; in other words, it is more relevant to one cultural group than the other. Similarly, culturally specific factors are those that may be related to offending (e.g., loss of Indigenous language) exclusively for one group. There is a dearth, however, of empirical research in the area of cross-cultural validity and exploring cultural differences in these risk factors.

Case Example: Risk Assessment With Indigenous Offenders

Within the larger debate concerning risk assessment with minority offenders, many have specifically questioned the applicability of these tools with Indigenous offenders, given their overrepresentation in the criminal justice systems of Canada, Australia, and New Zealand. For example, in Canada, in 2016, Indigenous peoples represented one quarter of federal inmates, while only accounting for approximately 4% of the general population. One of the main arguments explaining their overrepresentation is the differential history and experience of Indigenous peoples compared to non-Indigenous people. Namely, it is argued that the history of colonization, isolation, and discrimination has resulted in Indigenous peoples disproportionately coming into contact with the justice system. Therefore, in order to better understand criminal behavior among this population, this cultural history must be considered in any assessment of risk.

In Canada, risk assessment instruments developed on non-Indigenous male offenders are, for the most part, also administered to Indigenous offenders. Meta-analytic reviews on the predictive validity of common risk factors (i.e., the Central Eight risk/need factors, as defined by Andrews and Bonta in 2010) and assessment tools (e.g., the Level of Service Inventory Scales) have shown, with consistency, that risk factors and assessments generally predict recidivism for Indigenous offenders (as is similarly found with other racial minority groups); however, they do so with less predictive accuracy than with White offenders. Given the unique history of Indigenous peoples, it has been suggested that culturally relevant and culturally specific factors may be important to better understand criminal behavior among this population.

Gender

The steady increase in female involvement in the criminal justice system, and a lack of similar growth in male offending, has prompted considerable interest in the assessment and management of female offenders. Given the emphasis on evidence-based practice, this had led to increasing questions

regarding the applicability of standard risk assessment tools, largely developed on male offenders, to female offenders. The criticisms associated with applying existing assessment tools to female offenders are premised on evidence indicating that female offenders differ significantly from male offenders in both offending patterns and personal/social histories. Compared with males, female offenders are most often arrested for alcohol- or drug-related offenses, minor property crimes, or public order offenses. They typically experience increased rates of social marginalization and poverty, physical and sexual abuse as children and adults, substance use problems, mental illness, and are more likely to be primary caregivers for children compared to male offenders. It has also been suggested that low self-esteem and self-efficacy, problematic relationships, and the experience of trauma are salient factors in understanding female criminality. Although male offenders also experience these issues, research has shown that these factors affect female offenders with greater frequency. Furthermore, it has been suggested that these factors uniquely impact pathways to crime for females and, in turn, have been referred to as *gender-responsive factors*. In contrast, risk factors typically referred to as *gender-neutral* are risk factors that are argued to apply equally to all offenders, such as the Central Eight risk/need factors.

The most commonly used risk assessment tools consist of gender-neutral factors and therefore, consistent with general theories of criminal behavior, they include the same items and weighting for all offenders; this implies that all risk/need items have the same relevance for both genders. When examining the extant literature, the predictive accuracy of existing, gender-neutral risk assessment tools, particularly those tools focused on dynamic factors, has been mixed when tested with female offenders. Beyond explanations associated with the tools themselves, these findings may be partially attributable to a lack of sufficient research to provide stable results. Overall, studies focusing solely on risk assessment with female offenders are few, though growing, and those studies that include female offenders within a larger sample do not consistently separate effect sizes by gender. Furthermore, even less is known about female offenders of diverse ethnic/racial backgrounds. One exception appears to be the Level of Service

Inventory instruments, as they have been the most tested risk assessment tools with female offenders and results generally suggest acceptable predictive ability, although questions about overclassification remain.

Feminist scholars have argued that even if gender-neutral factors (e.g., employment, relationship problems) are predictive for female offenders, they are experienced differently by female offenders and, therefore, differentially affect the offending patterns of this group. Burgeoning research has also suggested that using standard gender-neutral risk assessment tools that do not include or emphasize factors more relevant for female offenders produces inaccurate risk estimates associated with the overclassification of female offenders. In turn, as the role of risk assessment has extended beyond simply risk prediction to also informing treatment, it is suggested that these standard tools do not identify other, potentially more relevant treatment targets for female offenders.

The practice of simply validating the existing tools on female offenders does not explore the arguably differential mechanisms underlying the relationship between gender-neutral risk factors and female offending. It also does not assist in determining the existence of more predictive and appropriate risk/need factors, and therefore, treatment targets, for this offender group. These concerns with gender-neutral tools coupled with qualitative and mixed-methods research suggesting the importance of gender-responsive factors have led feminist scholars to call for gender-informed risk assessment tools. Evidence to support this view is growing, as some studies have found that gender-responsive risk factors (e.g., parental stress, adult victimization, childhood sexual abuse) have added incremental predictive validity to existing gender-neutral risk tools. In turn, researchers have begun to develop risk assessment tools specifically for female offenders, typically including both gender-neutral and gender-responsive risk factors.

OFFENDER RISK ASSESSMENT: RISK COMMUNICATION

In the context of offender risk assessment, risk communication is the process whereby the results of an assessment are conveyed in words, numbers, and/or pictures to decisions makers. The study of risk communication concerns the effect that the communication method, the characteristics of the individual receiving the communication, or the decision-making context has on people's decisions. Forensic risk communication is a relatively new area of forensic psychology arising from the

growth in offender risk assessment instruments since the 1990s. Its importance lies in its being the fulcrum of risk assessment's influence over forensic decision-making and hence over the expression of the risk principle within the Risk-Need-Responsivity model of correctional intervention.

This entry describes research into the communication formats and individual characteristics that influence risk perception and related decision-making, drawing on lessons learned from medical risk communication research, then focusing on violence risk communication. It reviews the effects of how numbers are presented, the role of individual numeracy, and the communication of risk in terms of probabilities or risk categories. This entry considers what existing research suggests for best practice in offender risk communication.

The Importance of Forensic Risk Communication

In 1984, researchers Vladimir J. Konečni and Ebbe B. Ebbesen published a critical account of judges' decision-making in criminal and mental health cases, describing them as "almost 100% rubber-stamping" the recommendations by psychiatrists, prosecutors, and probation officers. This pattern, in which both criminal courts and mental health review boards rely heavily on the risk assessment results and recommendations communicated by assessors, was replicated several times over the next three decades. Studies showing that advice provided by clinicians or other assessors is a substantial influence on forensic decision-making raise the importance of not only assessing risk accurately but also understanding how to communicate risk effectively.

Lessons From Medical Risk Communication

The evidence base for forensic risk communication draws key lessons from medical risk communication. For example, information that is framed in terms of the possible risks of inaction (negative framing) is effective for persuading people to assess their health, but framing information in terms of the benefits of treatment (positive framing) is more effective for persuading people to choose treatment. Numeracy helps medical

patients understand their risks better, and more numerate individuals are more likely to remember and use mathematical reasoning in their decision-making. However, even educated professionals struggle with numeric information.

Research into the communication of medical and other risks has found that the effects of risk *illiteracy* can be alleviated to some degree by communicating risks with the aid of graphs. Graphs can also help communicate the normalcy of a distribution and the unusualness of extreme outcomes. If used, graphs need to be purposely selected for their ability to communicate the gist of the relevant risk information and for their suitability to the purpose (e.g., identifying absolute risk of an unhealthy behavior vs. conveying the relative risks of treatment options). Any verbal description of the graph should be carefully written and tested to ensure that it is congruent with the graph and does not introduce the potential for misinterpretation.

The Framing of Risk

As found in medical research, how the risk is framed can influence violence risk perception. In forensic risk communication, risks are usually framed negatively, in terms of the likelihood of recidivism. Some assessments have been developed in which the items are phrased so that a positive score indicates lower likelihood of recidivism, drawing attention to the outcome of not offending, that is, positive framing. Research indicates that positive framing leads to more decisions to discharge offenders from custody than does negative framing. For instance, one study revealed that a risk described as a 26% chance of violence occurring was perceived by mock judges to be more dangerous than a 74% chance of no violence occurring, even though both statistics refer to the same probability of events. Graphs have been considered helpful in communicating such risks, partly because they can show simultaneously the probability of violence occurring and the probability of it not occurring, as in icon arrays.

Some research finds that risks also seem higher if they are communicated using frequencies (i.e., the number of recidivists per 100 or 1,000 offenders) rather than probabilities or percentages (e.g., .40 or 40% likelihood of recidivism). Again,

graphs might be beneficial to the extent that they can be used to show information in frequencies and percentages at the same time. Different graphs might be employed to illustrate alternative framing or varying scales, which can also influence how risk is perceived, and each should be carefully designed and evaluated for its intended purpose. Also, the numeric information in graphs can still be difficult for less numerate individuals to understand.

Numeracy

There is evidence that numeracy affects how risks are perceived and used in forensic cases. In general, people tend to overestimate the risk of violent offending and ignore how common recidivism is in the whole forensic population (i.e., the base rate). Offender risk can be perceived as higher if case information that is unrelated to risk is communicated at the same time as the risk assessment, and there is evidence that decision makers in the corrections system often override the results of structured risk assessment using information that is unrelated to risk. More numerate individuals appear to be less swayed by such peripheral information. Less numerate individuals are more likely to be influenced by anecdotal and affective information rather than numeric information provided in forensic evidence.

As well as numeracy, experience with risk assessment information and attitudes toward social science and evidence-based practice has been associated with how risk information is understood and used in decisions. Graphs can increase people's attention to the probability of harm and for that reason have the potential to be especially helpful for communicating the risk of violent behavior, but research evaluating the use of graphs in forensic risk communication remains very limited.

Numerical and Categorical Communication of Risk

Offender risk assessment is generally conceived of as prognostic rather than diagnostic, and the results of risk assessment make a statement about the likelihood of offending in the future. As a result, risk may be expressed as a probability.

Actuarial risk assessment instruments typically yield an empirically derived probability of recidivism associated with categories of risk, although these categories may be determined through a rational process. For risk communication, advantages of using actuarial data include the precision and reliability of assessment results. Effective communication of actuarial risk can aid the allocation of risk management resources to individual offenders according to their risk of offending, which supports the efficiency and effectiveness of the correctional system. However, some discussion remains in the literature as to which statistics are the most important to communicate (e.g., relative risk vs. absolute probability of recidivism). Furthermore, assessors and decision makers are not always comfortable with the use of statistics.

Risk assessments that take a structured professional judgment approach typically result in a non-numerical risk category such as *low risk* or *high risk*. A practical advantage to the use of categorical risk communication is that clinicians are more accustomed to a diagnostic than a probabilistic approach and prefer using categories. However, as with medical risk communication, people do not interpret these risk categories consistently. Variation in the interpretation of risk is a problem for the practice of risk communication because it is difficult to agree on a disposition or the allocation of correctional resources if different assessors and decision makers each have a different idea of what an offender's risk category means. Reformulations of structured professional judgment tools in the mid-2010s emphasized case formulation rather than categorization, aiming to integrate the analysis of risk factors with suggestions for risk management. Initial research examining the communication of risk management recommendations to law enforcement, social service, and correctional agencies suggests that most recipients carried out at least some of the recommendations, especially those affirming court-ordered conditions.

Recommendations for Practice

In their foundational article, Vladimir J. Konecni and Ebbe B. Ebbesen conducted some of the first research into risk communication in real-life settings, and they looked forward to changes in forensic decision-making that allowed for a greater

role of analytic data and feedback provided to the decision makers. By 30 years later, risk assessment data were widely available, and there was growing evidence (experimental and naturalistic) that forensic decisions are made in accordance with the risk principle. However, studies suggest that clinicians, jurors, and other decision makers still do not necessarily view offender assessment, or key contributors to risk such as psychopathy, as a particularly important piece of information. To be effective, risk communication must help people overcome any existing misunderstandings (including a tendency to overestimate risk) and redirect their attention to relevant and useful information.

Effective risk communication helps people make a meaningful connection between risk information and decision-making. A standard for evaluating the effectiveness of forensic risk communication has been proposed that measures the distinction made in risk management decisions between offenders with measurably different risk of recidivism. Experimental research employing this standard has reported that providing numerical information can improve risk communication. Recommendations emerging from this line of research include explicitly tying any categorical risk communication to nonarbitrary numerical risk estimates.

The use of graphs has been recommended to facilitate the communication of offender risk assessment. Although there is limited empirical evidence pertaining to graphs in forensic decision-making, initial research suggests that a simple histogram of the proportion of offenders who recidivate as a function of assessed risk category can improve risk communication. Graphs used for this purpose should be selected with attention to negative and positive framing of information, and the benefits of presenting information in multiple formats should be evaluated.

Evidence that forensic decision makers rely heavily on information provided by professionals who assess risk points to the need for these experts to develop expertise in effective risk communication. Training in risk assessment techniques has already been successful; in the future, training in how to evaluate and explain offender risk assessments and their results might also be valuable. Assessors serving as expert witnesses must learn to help a nonscientific audience to overcome

misconceptions about risk and understand how statistical interpretations can be applied to decisions about individual offenders.

An emerging area of offender risk assessment is analytic procedures that demonstrate the ability to measure individual offenders' risk and its change after treatment. In the future, the practice of risk communication might also need to develop methods to communicate the extent and limits of change in risk.

OFFENDER RISK ASSESSMENT: USE OF THE PROFESSIONAL OVERRIDE

The underlying assumption of the professional override when applied to offender risk assessment is simple. After completing a structured, statistically based or actuarial assessment on a specific individual, the professional who is conducting the assessment may have what is believed to be additional, relevant information that was not taken into consideration when conducting the structured assessment. This occurs when the information is not relevant to the scoring of any of the instrument's items. The question then is, can or should the professional make some kind of

adjustment to the statistically derived results of the assessment? This is known as the *professional override*. This entry describes the background behind the professional override, its position in the history of offender risk assessment development, and the elusive quest to demonstrate its capacity to improve upon a structured, statistically based offender risk assessment.

The Professional Override

Applying a professional override to a statistical prediction scheme represents one attempt to reconcile a long-standing dispute between statistical/actuarial and clinical/professional judgment. The competition was kicked off in earnest with the classic work of Paul Meehl in 1954. However, since 1958, psychologists and criminologists, such as Robert Holt and Donald Gottfredson, have been advocating for clinically and statistically oriented researchers and clinicians to abandon their competitive attitudes and work more collaboratively.

In 1990, Donald Andrews, James Bonta, and Robert Hoge asserted that there were four key principles that contribute to the delivery of effective correctional treatment for offenders. Three of them became known as the *Risk-Need-Responsivity* model of offender intervention. The fourth principle, professional override, relates to the responsibility of professionals to go beyond the calculated application of Risk-Need-Responsivity when making decisions as to how to treat an offender in his or her particular circumstances. As such, it introduces an element of clinical judgment, also known as *professional discretion*, in the decision-making process. Perhaps the most common application of the override principle is in the context of a structured, statistically based offender risk assessment.

Because it is essentially a clinical judgment, the override bears some resemblance to, but is not quite the same as, the structured professional judgment approach to offender risk assessment. While use of the override is considered an *add-on* to an existing assessment, structured professional judgment assessments are based on stand-alone assessment instruments, and while structured professional judgment assessments are standardized

in the sense that they comprise specific risk items (often 20), the override knows no bounds in terms of content, or risk factors, that it may consider. Yet they are similar in that both are fundamentally subjective in their approach to decision-making about offender risk.

Use of the Professional Override in Offender Risk Assessment

There is well-documented evidence, summarized in meta-analyses by William Grove and colleagues, that statistically based predictions are superior to clinical judgment in fields as diverse as education, health, financial success, and criminality. Yet there remains a sense that criminal justice professionals may contribute their own insights to the prediction of offender behavior, at least as an adjunct to statistically based predictions. Every offender is unique in many ways, and clinical professionals are experienced with working on a one-to-one basis with offenders' uniqueness. Hence, it seems natural to give professionals an opportunity to contribute their own particular insights to the understanding of an offender and the prediction of his or her future behavior at the idiographic or individual level. It is assumed, either correctly or incorrectly, that override decisions are based on sound theory and research on offending behavior. Andrews and colleagues also believed that research on the consequences of overrides would lead to new insights into offending behavior and its amelioration.

Two of the most popular offender risk assessment instruments in North America allow for the professional override. Versions of the Level of Service Inventory have incorporated the professional override in their administration protocol. Although the Level of Service Inventory-Revised manual provides cutoff scores to denote various levels of risk, it declares that these cutoff scores should be used only as *guidelines* in conjunction with "good sound judgment by experienced professionals" (p. 14). The more recent Level of Service/Case Management Inventory (LS/CMI) and its youth version both formalize the override function by building it into the assessment protocol. Assessors are explicitly instructed to indicate whether or not they wish to exercise the override option and if so, why, in their professional

opinion, its use is warranted. They may then assign a higher or lower risk level to the offender than what was derived from the numerical score on the assessment.

Another popular instrument, the Correctional Offender Management Profiling for Alternative Sanctions, also allows the criminal justice professional to make a final judgment regarding an offender's risk level. Correctional Offender Management Profiling for Alternative Sanctions software includes a Screener Judgment tab, on which several questions are asked that allow assessors to introduce their own overall conclusions about an offender's risk. They are asked to consider *aggravating* factors (e.g., resistant to treatment), which may render an offender higher risk than what was determined by the statistical analysis, and *mitigating* factors (e.g., being crime free for many years), which may render an offender lower risk. Correctional Offender Management Profiling for Alternative Sanctions authors expect that assessors will override offenders to a different risk level than what was assigned statistically in 8–15% of assessed cases.

Some sexual offender risk assessment instruments also include override features. The Minnesota Sex Offender Screening Tool–Revised provides eight guidelines for assessors to increase sexual offenders' risk level and one guideline to reduce it. The Static-99 initially gave clinicians considerable discretion to use the override but has since tightened that position in accordance with research described in the following section.

It should also be noted that some instruments, including the LS/CMI and the U.S. Federal Post Conviction Risk Assessment, allow for an *administrative* or policy override. These are cases when the override feature is exercised, not for clinician or professional reasons, but for policy reasons determined by the correctional agency. It may be applied to sexual offenders, mentally disordered offenders, and those who, for various reasons, are high-profile offenders.

Research on Use of the Professional Override in Offender Risk Assessment

As a precursor to the professional override in offender risk assessment, some early efforts were made to amalgamate actuarial risk assessment

with human judgment. One study examined whether some combination of the Correctional Service of Canada's risk assessment tool, the Statistical Information on Recidivism Scale, might dovetail with decisions by the National Parole Board to arrive at a better overall prediction of offender recidivism. By combining independent Parole Board decisions with offenders' Statistical Information on Recidivism scores, a modest improvement in the prediction of offenders' recidivism was found over predictions based on the Statistical Information on Recidivism score alone. However, most of the subsequent override research has been less encouraging. This research falls into two categories, studies that have examined the override with general risk scales on general offender populations and studies that have examined its use with sexual offender instruments on samples of sexual offenders.

When correctional workers were first given the opportunity to apply the professional override to a group of probationers and provincial prisoners using a draft version of the LS/CMI (Level of Service Inventory: Ontario Revision), the professional override was used in only 3% of the cases, with increases and decreases in risk being approximately equal. After the override option was given, the final risk level correlated slightly higher with recidivism than the initial risk level. When the LS/CMI was implemented on a system-wide basis in Ontario, subsequent studies documented much greater use of the override (12–17%), primarily to increase risk and disproportionately on sexual offenders, and found it had a negative impact on predictive validity.

Research on the use of the override with the STATIC-99 has found that assessors could not agree on which cases to use the override, and in which direction to do so, beyond a chance level of agreement. Moreover, its use decreased the predictive validity of the instrument. This led STATIC-99 authors to suggest using the override only in conjunction with other statistically based instruments. Nonetheless, field studies have found the override has been applied to the STATIC-99 in as much as one third of the assessments and often without the support of another statistical tool. Not surprisingly, such practice again reduced the predictive validity of the instrument.

Not to be confused with the professional override, research after the initial publication of the STATIC-99 led its authors to provide directions to modify the risk assessment of sexual offenders based on factors such as age. However, these *adjusted actuarial estimates of risk* are strictly statistical modifications of assessed risk and therefore not professional overrides. They have also generated some degree of controversy.

Research on the Minnesota Sex Offender Screening Tool-Revised has found a surprisingly high use of the override (from three quarters to almost all cases). The effect of the override was to move offenders, both high and low risk, toward the median risk group. The impact of this practice was to reduce the predictive validity of the instrument slightly.

Future of the Professional Override in Offender Risk Assessment

Empirical evidence for the incremental predictive validity of the professional override remains elusive. It is quite possible that part of the difficulty comes from the very nature of professional discretion. Specifically, its variability and complexity defies easy quantification and systematic investigation. While some have come to deny any role for professional discretion in offender risk assessment, others continue to advocate for its controlled use as part of a long-standing effort to improve the prediction of offending behavior. Most would agree that any effort to apply the override to field settings would require ongoing monitoring and research to direct and guide such a practice.

OFFENDER RISK ASSESSMENT AND RISK LEVEL CLASSIFICATION ISSUES

The development and proliferation of risk assessment tools have allowed corrections professionals to assess an offender's risk to reoffend and determine the needs underlying his or her criminality. Not only are risk tools the engine that drive effective interventions with offenders, but they help agencies be more efficient by helping them identify those offenders that need the most intensive intervention and that pose the most risk to reoffend.

Current risk assessment instruments help agencies identify *who* should receive the most supervision or intervention to reduce their risk of recidivism (i.e., higher risk offenders) and determine *what* specific factors should be targeted to change criminal behavior. These factors are called *criminogenic needs* (i.e., factors that are strongly correlated with criminal behavior and are dynamic in nature). Through years of study, researchers have identified the major criminogenic needs of

offenders: (a) antisocial attitudes, values, and beliefs; (b) antisocial peers; (c) antisocial personality characteristics; (d) family; (e) education/employment; (f) leisure/recreational activities; and (g) substance abuse. This entry provides a general overview of offender risk assessment practices and processes, reviews the history and current *state-of-the-art* of risk assessment instruments, outlines some common practical and methodological issues related to their use and implementation, and examines related risk level classification issues.

What Are Offender Risk Assessment Tools?

The process of identifying an offender's risk level and corresponding criminogenic needs is known as offender risk assessment or offender classification. Put simply, *risk* refers to an offender's likelihood to recidivate or to get into trouble again. Thus, offenders who are at high risk are more likely to reoffend, compared to offenders who are at low risk. In a similar vein, research indicates that a reduction in an offender's risk level is typically associated with a reduction in his or her likelihood of recidivism, while an increase in an offender's risk level is typically associated with an increase in his or her likelihood of recidivism.

Commonly used instruments consist of actuarial risk assessments that are similar to what insurance companies use to calculate insurance rates. Car insurance rates, for example, are based on the statistical analysis of a person's driving records and other supplemental information (e.g., age, where the driver lives, type of car he or she drives), which helps insurance companies develop probability tables based on group behavior. A probability table, for instance, may indicate that someone is a high-risk driver due to his or her history of car accidents and speeding tickets, where he or she currently resides, and the type of car he or she drives. Similarly, in the field of corrections, a risk assessment tool may indicate that someone is a high-risk offender due to his or her criminal history, use of illegal substances, and unemployment status. Ultimately, insurance companies and criminal justice professionals alike can use the results of actuarial risk assessments to determine who is riskiest to commit a new driving offense or a new criminal offense, respectively.

Actuarial-based instruments used in the field of corrections today typically consist of a series of items that focus on those factors that have been found to be related to criminal behavior (e.g., antisocial peers, substance abuse). Items on the tool are then statistically weighted based on how strongly they correlate with recidivism, and an overall score is calculated that identifies the individual's risk to reoffend. The corresponding risk level and information related to the offender's unique areas of need can then be used to help guide decisions about whether to sentence the offender to prison or probation, his or her conditions of supervision, and the types of resources that will be used, all while enhancing public safety and security.

History of Offender Risk Assessment

The first generation of risk assessments relied on corrections professionals' judgment and experience (i.e., their *gut feelings*). While information was collected through a face-to-face interview and a review of the offender's file, prediction about their likelihood to reoffend was made based on the assessor's *professional opinion*. In this way, there was no structured or standardized set of questions to be asked, so the assessor could ask the offender as many or as few questions as the assessor deemed appropriate. Ultimately, decisions based on this approach were idiosyncratic, subjective, and biased. Furthermore, this approach did not yield information that resulted in a distinction between risk levels.

The second generation of formal classification instruments was first developed by Andrew Alexander Bruce and his colleagues in 1928 at the request of the Illinois Parole Board. The Illinois Parole Board, more specifically, wanted to make more informed decisions about whom to release and when to release individuals back into the community. As such, Bruce and his colleagues collected background information on more than 3,000 parolees related to criminal history, personal characteristics, and prison experience and found 21 factors that differentiated those offenders who successfully completed parole from those who failed to complete parole. While some of the factors measured on the Bruce and colleagues' *Burgess Scale* seem out of date (e.g., criminal type,

social type, statement of trial judge and prosecutor), other measures appear on many validated risk assessment instruments used today (e.g., previous record, where offender resides, marital status).

The Burgess Scale was one of the earliest examples of an actuarial-based risk assessment tool, but along with other later-developed tools, such as the Salient Factor Score, these types of instruments have several limitations. One of the primary limitations, for instance, is that they are almost all based on static predictors: items that cannot change (e.g., criminal history) or cannot be easily influenced (e.g., age or months served prior to parole). To the extent measures other than criminal history are examined, such items capture only historical data. That is, second-generation tools may examine factors such as whether the offender had a substance abuse problem or whether the offender associated with other criminal associates, but these factors can only be examined from a historical perspective rather than a current perspective.

Third-generation instruments represented a major advancement in risk assessment since they incorporated both static and dynamic risk factors. Recall that dynamic risk factors are those items related to criminal behavior that can be changed, such as getting a job, stopping illegal drug use, or spending time with others with criminal behavior issues. Importantly, third-generation instruments such as the Level of Service Inventory–Revised can be used for both initial assessment and reassessment to measure offender behavior change over time.

Finally, the latest generation of risk assessment tools—fourth-generation instruments—is comprehensive in that they include both static and dynamic risk factors as well as take into consideration factors or barriers to treatment and intervention (e.g., lack of motivation, low intelligence, mental health issues, physical disabilities). While these are not risk factors per se, they are related to case planning and can help practitioners properly match offenders to treatment and intervention strategies so that their likelihood of success can be maximized. In addition, fourth-generation tools, such as the Level of Service/Case Management Inventory, the Ohio Risk Assessment System, and the Correctional

Offender Management Profile for Alternative Sanctions, incorporate case management strategies to more clearly link risk assessment results with intervention and treatment strategies.

Types of Assessment Tools

There are three unique types of risk assessment tools. Screening instruments are designed to allow corrections professionals to determine outcome (e.g., recidivism) for a large offender population (usually at intake) and, subsequently, sort those offenders into risk categories relatively quickly. A screening instrument, for example, may be used to *screen out* low-risk offenders so that a more comprehensive risk assessment may be completed on those offenders who are at moderate risk to high risk. Notably, screening tools can be completed by a file review and/or a brief face-to-face interview, as they are usually composed of only static items (e.g., criminal history). The tools, however, have little utility beyond identifying levels of risk due to their limited number of dynamic items.

In addition to screening tools, comprehensive risk/need assessments are designed to gather more complete data to assist in determining levels of risk. Risk/need instruments typically take longer to administer, require training, and can be used to identify targets for treatment. These instruments include a range of dynamic factors that can be used to reassess the offender. Furthermore, composite risk assessments can be used to develop case plans to ensure that programming targets the criminogenic needs of the offender.

Once a comprehensive risk assessment is completed, specialized assessments can be used to assess specific domains (e.g., substance abuse) or special populations (i.e., sex offenders, mentally ill offenders, psychopaths). Specialized assessments, in particular, may be completed on offenders who are flagged as risky on a composite risk/needs tool. These instruments usually require additional training on the part of those who administer the assessments, while some tools require special licensures to conduct.

In many instances, jurisdictions adopt all three types of assessments. A screening instrument might be used at pretrial or to assess offenders at intake to determine who needs further assessment. For those offenders who continue deeper into the

system, a more comprehensive assessment tool could be used. Once assessed on a composite risk tool, a specialized assessment may be prescribed on an as-needed basis. Following this approach can increase efficiency since not all offenders will be thoroughly assessed, but those offenders who appear to pose the greatest risk to reoffend will be examined much more closely.

Widespread Use of Risk Assessment Tools

As of 2017, risk and needs assessments are used at nearly all points in the criminal justice system across the United States, including pretrial, sentencing, probation and parole, and prison intake and reentry. Although evidence exists to show that risk assessment tools are widely used across the country, variability exists in terms of which tools are used and how they are implemented within a specific agency or department. For example, some states may adopt and implement one standardized instrument that is used across each sector of the criminal justice system and throughout the entire state. Other states, however, may take a less systematic approach and allow different criminal justice entities to choose their own method for assessing and classifying offenders.

Beyond the support for use of validated risk assessment instruments given at the national, state, and local levels, evidence exists that legislative action and statutory changes have taken place in response to risk assessment instruments. For example, in Indiana, the Supreme Court held that judges may consider risk assessment tools to supplement other evidence when making decisions about whether to sentence offenders to probation, alternative treatment facilities or programs, and other corresponding sentencing matters. Additionally, some grant administrators and criminal justice policy development agencies, such as the Bureau of Justice Assistance, oftentimes require or strongly suggest that agencies responding to funding solicitations use a validated risk assessment instrument to ensure they are adhering to evidence-based practices.

Risk Level Classification Issues

Overall, research suggests that the more commonly used risk assessment instruments used in the field can, with a moderate level of accuracy,

predict who is at risk of recidivism. In addition, research suggests that when it comes to the predictive validity of the tools (i.e., whether the tools are measuring what they are supposed to be measuring), no one instrument is better or more superior than another at predicting recidivism. To this end, it is not necessarily about *what* instrument is being used (as long as it is an appropriate, validated tool), but about *how* the instrument is being used.

There are a number of important considerations with any risk/need assessment process that need to be considered. For example, how easy is the instrument to use and score? How long does it take to complete? How much training is involved? Is an interview involved, and if so, how is the information verified? How much does it cost? Beyond some of these more practical issues, there are also a number of methodological issues. Of vital importance, for example, is ensuring the instrument is both reliable and valid. Reliability refers to the consistency of the instrument. For instance, if two individuals were to conduct an assessment of the same offender, how similar would they score him or her? This is referred to as *interrater reliability* and can be problematic with more dynamic instruments. The second important consideration is validity or the accuracy of the instrument in predicting what it is we want the tool to predict (e.g., recidivism). Both reliability and validity are important because an accurate tool is useless if no one can agree on the score. Likewise, there might be agreement as to the score, but if it does not predict what is hoped for, then it does not lead to the goals of reducing offender recidivism and enhancing public safety. As a general rule, most *good* instruments are about 70% accurate. This is determined by validation studies in which the correlation between the total score and the outcome of interest (usually recidivism) is examined.

Considerable issues may also arise when agencies or departments fail to use risk assessment instruments properly. Improper use of a risk assessment tool, for instance, may lead to high-risk offenders being released from community supervision or prison before they receive an appropriate level or amount of treatment to reduce their risk. Conversely, if low-risk offenders are given too much intervention, such as

being placed on intensive supervision or being sentenced to a correctional institution for an inappropriate length of time, they use valuable, oftentimes scarce resources that could be directed toward higher risk offenders. Perhaps even more important, treating low-risk clients and/or mixing them with high-risk clients has the potential to increase recidivism rates. Low-risk offenders' rates of reoffending may increase because placing them on higher levels of supervision and providing treatment often means taking away what makes them low risk to begin with (e.g., prosocial peers, supportive family, stable employment). In a similar manner, research suggests that when low-risk offenders are mixed with high-risk offenders in treatment and supervision settings, lower risk offenders oftentimes learn things from higher risk offenders that they may not have known before (e.g., where to buy or sell drugs).

Issues related to the use of third- and fourth-generation risk tools may also arise since these instruments include a variety of dynamic risk factors. That is, the *human* element or staff biases can oftentimes get in the way of any scoring or decision-making processes underlying the tool because they require the assessor to make subjective judgments. In this vein, what makes modern-day risk assessments advantageous (i.e., their dynamic measurement of risk factors and the quality and range of information collected) can also make them disadvantageous because they may require more specialized knowledge or training on how to use the tools, and/or a deeper understanding of the assessment process, in general.

Finally, another major concern is related to the use of a risk assessment tool in one jurisdiction when it has been constructed and validated in another. Undoubtedly, the development of a standardized risk instrument is often costly and the option that very few criminal justice agencies have the time or financial resources to construct. In this way, many adopt an *off the shelf* tool that may be empirically derived but has been constructed for a different target population. While some may argue that using a tool that has been validated on other samples is better than using no instrument at all (or a nonvalidated tool), agencies run the risk of using a tool that may not be predictive for their population. In addition, they may be placing

offenders in the wrong risk groups, as cutoff scores for the tool may not be appropriate. Given that it is unlikely for a single instrument to have universal applicability across various offender populations, there is a clear need to norm (i.e., determine what is typical in a given population) and validate risk instruments and their corresponding risk scales for the population for which it is being used.

Final Thoughts

There are a number of reasons that the effective classification and assessment of offenders is important in corrections. First, results of the instrument can be used by practitioners and other corrections officials to make important decisions, such as who should be released on parole. Second, it helps reduce bias by eliminating extralegal factors from consideration, such as race and gender. Third, it enhances public safety by allowing correctional professionals to identify higher risk offenders. Fourth, it helps corrections professionals manage offenders in a more efficient manner. That is, it aids in the development of offender caseloads and workloads that are based around risk and needs so that scarce resources can be reserved for those who need them most. Fifth, the use of risk assessment instruments helps staff justify their decisions and diminish legal challenges when they arise. Ultimately, using validated instruments that are backed by science and incorporate a structured process to make decisions is more defensible than relying on *gut feelings*. The sixth, and perhaps the most important reason to conduct good assessments of offenders, is that it improves the effectiveness of correctional programs.

OFFENDER TREATMENT ATTRITION

Treatment attrition, or the failure to complete treatment and to successfully fulfill program requirements, is a long-standing issue in the treatment of men, women, and youth who break the law. *Treatment* refers to a broad collection of interventions within a structured program, often delivered in a group format by a therapist (e.g., psychologist, social worker, licensed professional counselor). *Attrition* means essentially to gradually wear down or decrease, and this term has been used to describe the process of offenders *dropping out* of treatment (i.e., treatment noncompletion). Since treatment has numerous intended benefits for offenders (e.g., reducing their risk of reoffending and improving their chances of returning to society offense free), treatment attrition has negative consequences for the offenders and others. While there are numerous explanations for why offenders sometimes do not complete the treatment or programs they need, it is a common problem in the criminal justice system and one that is important to address. When offenders do not complete the treatment program they need, they may not lower their risk of reoffending, they may not learn new skills to transition into the community, and they are therefore at risk of returning to custody. This entry reviews the types, frequency, and key predictors of treatment attrition for offenders and then explores links to recidivism.

Types

Treatment attrition can occur in many ways. In the first type of attrition, offenders may leave treatment without completing for reasons of their

own doing, and in this instance, they actually do *drop out*. These are referred to as *patient- or client-initiated reasons*, including loss of motivation, a request to leave treatment or to transfer, or the individual sabotaging his or her own progress by acting out. A second way is staff-initiated attrition. In this circumstance, the staff member (e.g., therapist, program facilitator, security staff) initiates the offender's removal from therapy for a variety of reasons, including a lack of progress or effort displayed by the individual, disruptive or treatment-interfering behavior that can interfere with the progress of other clients, violating institutional rules, or posing security concerns. The third type of attrition is administrative, and this occurs when forces attributable to the agency or the system contribute to an offender's early discharge from treatment. These factors tend to be outside of the individual's control but can include being paroled, having the program assignment canceled, or being transferred out of the institution for reasons unrelated to treatment or behavior (e.g., population management).

Frequency

The problem of offender treatment attrition varies depending on the definition used and the type of offender group and treatment program under consideration. In a meta-analysis of 114 treatment attrition studies that included over 41,000 offenders who attended an offender treatment program of some sort, the average rate of attrition was 27%. In other words, roughly one quarter of individuals who started an offender treatment program did not formally complete it. This compares to an average noncompletion rate of about 20% in the adult psychotherapy literature. However, if those offenders who registered for a program but who dropped out before even attending the first session (i.e., preprogram attrition) are included, the rate of offender treatment attrition increases to 35% or about one third of offenders.

The rate of attrition has also been found to vary by type of offender and treatment program. For instance, the rate of attrition from sex offender programs is the same as the overall rate of attrition from offender programs in general (27% noncompletion). However, the rate of attrition from domestic violence programs (i.e., men

who are physically abusive toward their intimate partners) is 38%, and when the definition is expanded to include preprogram attrition, the rate of noncompletion is 51%. Researchers in this field have also found that community-based programs tend to have higher rates of attrition than prison or other institutionally based programs, probably in part because institutionalized offenders constitute a captive audience. In addition, opportunities for early conditional release are often dependent on the successful completion of required treatment programs, which can create an additional incentive to complete treatment while in custody.

Predictors

What predicts whether an offender is likely to complete, or not complete, a treatment program? There are many factors that come into play. The meta-analysis of 114 studies referenced previously not only examined rates of noncompletion from different offender treatment programs but also the predictors of noncompletion. The following are common predictors of attrition across offender programs in general:

<i>Demographic Predictors</i>	<i>Offense History Predictors</i>	<i>Psychological Predictors</i>
• Young age	• Prior offenses	• Antisocial personality disorder
• Single	• Prior violent offenses	• Psychopathy
• Low education	• Shorter sentences	• Borderline personality disorder
• Unemployed	• Institutional offenses	• Low IQ
• Ethnic/racial minority	• Previous incarceration	• Impulsivity
• Low income		• Anger problems
		• Drug and alcohol problems

These characteristics predict attrition for a variety of reasons (i.e., each predictor has its own relationship to attrition), but it is beyond the scope of this entry to go into detail for each. Broadly speaking, several demographic characteristics predict attrition across programs: On average, offenders who do not complete treatment are more likely to be younger, have less formal education, be unemployed, be single, have low income, and be a member of an ethnic/racial minority group. However, this does not mean that having such characteristics causes offenders not to complete treatment, but rather these are correlates. Although these characteristics may serve as markers to indicate an offender who is vulnerable for not completing treatment, there are many men, women, and youth with these characteristics who do successfully complete treatment. Moreover, offenders with more serious offense histories of most varieties, who have previously been incarcerated, are serving a shorter sentence, or who have a history of institutional misbehavior are at an increased risk not to complete treatment. Certain psychological characteristics are also linked to higher rates of attrition, including having a serious personality disorder associated with disruptive and unstable behavior; having low IQ; or having problems with impulsivity, anger control, or substance use.

Many of the very characteristics that predict noncompletion also tend to characterize high-risk offenders, that is, many of these attrition risk factors are also risk factors for recidivism. In fact, research has shown that some of the common risk assessment tools used to predict recidivism also predict treatment noncompletion. It is the case that higher risk offenders are less likely to complete treatment than lower or more moderate risk offenders. However, many high-risk offenders do complete treatment, and Donald Andrews and James Bonta's risk principle points out that when high-risk offenders complete treatment, this tends to generate the largest payoff when it comes to crime reduction.

Specialized Offender Treatment Programs

Some characteristics that tend to be unique to the type of offender and treatment program have implications for attrition. For instance, sexual deviance tends to be an important risk factor for

recidivism among sex offenders, but research has found on average that sexual deviance is not a very strong predictor of sex offender treatment noncompletion; whether or not the men complete these programs has more to do with the factors listed and discussed previously than with their levels of sexual deviance. For domestic violence programs, research has additionally found that men who are court ordered to attend treatment and who have been in longer relationships are more likely to complete treatment and less likely to drop out; however, men with more serious histories of domestic violence are still less likely to complete.

Links to Recidivism

It appears then that treatment attrition is associated with increased recidivism. Put simply, offenders who do not successfully complete their treatment programs are more likely to return to custody (e.g., jail, prison) for new offenses. This applies to all recidivism outcomes. For instance, treatment noncompletion in general is associated with a 20% increase in recidivism. Similarly, sex offender treatment attrition has been found to be associated with an approximate 15% increase in rates of sexual recidivism, and attrition from domestic violence programs has been associated with an approximate 18% increase in domestic violence recidivism. The logical conclusion to draw is that failure to successfully complete a treatment program means the offender has not made treatment gains, which has resulted in recidivism; however, these are merely correlations. For instance, do offenders who fail to complete treatment reoffend at a higher rate because they did not benefit from treatment, or because they were already higher risk offenders to begin with? While both factors likely contribute to what may be a complex relationship, regardless of the precise mechanism involved, treatment noncompletion has linkages to increased recidivism; this highlights the need to retain high-risk offenders in treatment whenever possible.

Final Thoughts

Research has identified demographic, criminal history, and psychological characteristics associated with treatment attrition for offenders in general

and special populations and programs in particular. Many of these predictors of attrition also characterize high-risk offenders. For this reason, it is important that these predictors not be used to create an *attrition profile* (i.e., a list of reasons to exclude offenders from treatment, to assign them lower priority for services, or to expect them to fail). Rather, such characteristics should provide an incentive for programs and therapists to retain high-risk men, women, and youth in treatment so that they can benefit from services. By adapting services in ways that are responsive to specific predictors of, or characteristics associated with, treatment noncompletion (e.g., readiness for change, level of education, cultural background), high-risk offenders may be more likely to be successfully engaged and retained in treatment.

OFFENDER TREATMENT ATTRITION AND RETENTION, RESPONSIVITY ISSUES

The issue of offender treatment attrition (i.e., noncompletion) and retention (i.e., continuation), including the role of responsivity (i.e., the adaptation of offender treatment services to fit the

unique individual needs of client), is complicated. It is known that high-risk offenders are more likely to drop out, but paradoxically, they are also the group most in need of services. Therefore, by having knowledge of predictors of attrition as well as knowing how to respond to unique client needs, service providers could retain clients in treatment, providing them with a greater chance to benefit from services. Certain attrition predictors that seem to be linked to responsivity are known as *treatment responsivity indicators*. This entry further defines responsivity, then examines specific treatment responsivity issues that play a part in offender treatment attrition and retention, while offering management strategies to promote client retention and decrease dropout.

Defining Responsivity

Responsivity is the third prong in Donald Andrews and James Bonta's Risk-Need-Responsivity (RNR) model. It has two types: general and specific. General responsivity refers to the notion that offender treatment programs should follow cognitive behavioral methods to modify criminal behavior and thinking. It is extended to include several aspects of the relationship between the therapist and offender in which the therapist is also expected to be warm, patient, understanding, empathic, authentic, and to show humor. Specific responsivity involves the tailoring of treatment services to meet the unique needs and characteristics of the offenders themselves, including different levels of motivation, intellectual ability, literacy levels, cultural background and language, learning style, and personality.

In a meta-analysis of 114 offender treatment attrition studies, those variables that seemed to have direct links to general and specific responsivity were categorized as *treatment responsivity indicators*. Additional predictors of treatment attrition identified in the meta-analysis had general or specific responsivity implications.

Treatment Responsivity Issues in Offender Treatment Attrition

Offender treatment attrition in and of itself can be a responsivity issue in cases in which the fit between the client and treatment was sufficiently disrupted that noncompletion was the result.

Some of these treatment responsivity issues are discussed in the following subsections.

Disruptive Behavior During Treatment

Offenders who behave badly in treatment are also less likely to complete it. Disruptive behavior can include intimidating staff and fellow patients, verbal and physical abuse (e.g., assaults or threats), acting out in group (e.g., cracking jokes, heckling the facilitator), or counterproductive behavior outside of group (e.g., sexual intimacies with other patients residing on the treatment unit). This can be par for the course, so to speak, when working with high risk challenging clients. But rather than ejecting a patient from treatment for showing the very issues that brought them into treatment in the first place, it is the responsibility of treatment staff to make an effort to engage the client and to try to decrease the treatment-interfering behavior. Some examples include staff maintaining clear boundaries and setting limits with clients, trying to understand the function of behavior, avoiding power and control battles, skillfully handling delicate situations, or possibly drafting behavioral agreements with difficult clients. In addition, staff can also meet with clients individually to help them to develop skills to manage tensions and negative emotions (e.g., dialectical behavior therapy).

Negative Treatment Attitudes

When offenders have negative attitudes toward the therapy itself and the prospect of making personal changes, this is also linked to attrition. Some treatment programs can even be stigmatizing, for instance, attending sex offender treatment, which involves an admission of problems with one's own sexual behavior as well as revealing to others that one has committed a sex crime. William Miller and Stephen Rollnick have developed a powerful intervention strategy called *motivational interviewing* (MI), which has several components, the key ones being to express empathy, develop discrepancy, respond constructively to (i.e., *roll with*) client resistance, and support self-efficacy. For instance, one way of approaching negative attitudes is to validate to the individual that change is difficult and that there are other things the

individual would probably rather be doing than examining and working on his or her personal problems; however, unless the issue that brought the individual into conflict with the law and referred to the treatment program are dealt with, then there is little to stop history from repeating itself.

Denial

It is a natural human tendency to downplay shortcomings and in some cases to try to make a wrongful action out to not be as bad as it could be. It is not uncommon for offenders to initially refuse to accept that they have done something wrong, such as committing a serious crime (e.g., sexual assault) or engaged in certain aspects of it (e.g., penetrating or fondling the victim). Research has shown that denial is a common predictor of attrition and particularly common in sex offender programs. Sometimes MI strategies can be effective in helping a client work through denial, or simply allowing the passage of time while sitting in a group of individuals who have committed similar crimes can create a culture of acceptance and understanding. Some programs have taken an innovative approach in which they do not even discuss the offense but rather focus on addressing the psychological issues that led to the individual being accused for the crime in the first place.

Low Motivation

Those offenders in denial are perhaps best conceptualized as being in the early stages of change. James Prochaska's Stages of Change Model, originally used with health behaviors (e.g., smoking cessation), has been adapted for offender populations. Key stages include precontemplation (i.e., no intentions of making positive changes), contemplation (i.e., thinking about making changes to problem behaviors; however, positive action has yet to be taken), preparation (i.e., preparing to take corrective action but any such actions are new and inconsistent), action (i.e., consistent efforts of a behavioral nature are observed over a significant period of time, with lapses into problem behaviors becoming fewer and further between), and maintenance (i.e., behavioral gains are maintained over a

substantive period, typically years). Thus, interventions matched to an offender's stage of change may assist him or her to build greater motivation and decrease risk of treatment dropout. For example, it may be counterproductive to assign homework to offenders who are in a precontemplative stage of change. Use of MI strategies with precontemplative individuals, however, may assist offenders in understanding some of the positive benefits of changing problem behaviors and thus help move them along the continuum of change.

Cognitive Challenges

Given that many offenders have left school prematurely owing to antisocial attitudes, learning problems, or cognitive challenges which may be present at birth (e.g., alcohol-related neurodevelopmental disorder) or sustained later in life, possibly owing to their high-risk lifestyle (e.g., serious head injury), interventions need to be tailored to their level of academic achievement (e.g., reading level) and cognitive functioning (e.g., IQ). Low educational attainment and IQ are strongly correlated with treatment noncompletion and require special attention. Disruptive behavior while in treatment may be an effort to conceal deficits in functioning. Incomplete assignments may also be a reflection of such deficits rather than antisocial attitudes regarding the treatment itself. Assessments of cognitive and intellectual functioning (e.g., literacy, verbal and nonverbal problem-solving) may assist treatment providers to better understand the nature of any difficulties and adapt treatment materials, assignments, and expectations accordingly (e.g., use of concrete interventions and examples, less reliance on written materials or highly verbal interventions).

Trauma

Early childhood trauma is often cited as being an important responsivity consideration. However, in the treatment attrition meta-analysis described previously, only past sexual abuse was associated with treatment noncompletion in offender populations. Trauma-informed treatments may be helpful for some offenders; however, in the majority of cases, treatment for trauma alone is unlikely to reduce the likelihood of

recidivism. Treatment for trauma should be prioritized in conjunction with criminogenic or crime-related needs, and timed appropriately, so as to occur in a safe setting and after the development of coping skills which could be applied should destabilizing emotions be experienced as a result of trauma work.

Mental Health

In addition to trauma, there are other mental health concerns which have been associated with treatment noncompletion. One example is psychosis. Experiencing symptoms such as hallucinations (e.g., seeing or hearing things that are not real) and delusions (e.g., belief that one is being persecuted by malevolent forces) can understandably interfere with treatment progress, especially when these symptoms do not respond well to medication, or medication is taken inconsistently, or refused. Aside from monitoring and promoting medication adherence, staff members should be trained in mental health awareness, be aware of the signs and symptoms of psychosis, and be able to respond to clients in a patient, calm, and effective manner without destabilizing the situation. In addition to treatment of criminogenic needs, sometimes ancillary services may need to be provided to promote mental health and well-being to maximize client engagement and service effectiveness.

Personality Disorder and Psychopathy

Personality disorders associated with disruptive, impulsive, unstable behavior, and emotional volatility (i.e., borderline personality disorder or antisocial personality disorder) can present challenges to treatment service providers and are linked to attrition. Personality disorders also involve destructive patterns in interpersonal relationships, which would extend to staff and co-client relationships. For instance, individuals with personality disorder may *split* staff members (i.e., manipulate one group to side with them against another) or approach multiple staff members in search of fulfillment of a request or special favors. Some clients may also transgress staff member boundaries or try to convince them to violate institution rules (e.g., bringing in contraband).

Psychopathy, a particularly serious clinical construct characterized by callousness, remorselessness, grandiosity, and manipulation, is associated with many of the aforementioned treatment-interfering behaviors and also linked to high rates of attrition. Experts in the area of psychopathy treatment recommend service providers to adopt a united front, maintain clear lines of communication, and work together to contain treatment-interfering behaviors of psychopathic offenders; many of these strategies would extend to other personality disordered clients. Doing so can result in retaining these clientele in treatment so that they may potentially benefit from risk reduction services.

Final Thoughts

The responsivity issues reviewed here are not an exhaustive list but highlight the many unique challenges clients bring to therapy which require services to be adapted so that such clientele do not add to dropout statistics. Difficult client behavior and the unique demands of challenging clients can be managed effectively by applying the principles of general and specific responsivity and ensuring relevant staff training. Techniques such as MI have considerable promise in mobilizing resistant clientele. Indeed, research has demonstrated that successful completion of offender treatment is associated with greater amounts of change derived, but to achieve this, even difficult clients need to be retained in treatment.

OFFENDERS WITH COGNITIVE DISORDERS

People with cognitive impairments are at greater risk of involvement in the criminal justice system, both as young people and as persistent adult offenders. This entry describes the wide range of cognitive impairments, and the disorders through which they typically manifest, and considers the relationships between cognitive impairments and criminality.

Cognitive Impairments and Related Disorders

Cognition is a general term for the mental processes involved in acquiring new knowledge and applying existing knowledge. It therefore incorporates a range of specific processes, including those associated with attention, comprehension, memory, reasoning, evaluation, and decision-making. It is also closely related to the comprehension and production of language and to thinking, perception, and imagination.

Such processes can be unconscious and automated, as is the case when performing a task with which one is very experienced, such as riding a bike. Alternatively, they may require executive control—that is, the ability to coordinate and direct thought and action toward complex goals through processes such as the initiation, planning, and sequencing of complex tasks; the utilization of long-term memory; concentration; inhibitory control; and responsivity to changing circumstances. Brain imaging studies have demonstrated that such higher order cognitive functions engage the prefrontal cortex, in combination with various posterior areas of the brain, depending on the nature of the task. In contrast, automated or unconscious acts may only utilize posterior areas of the brain.

A cognitive impairment can refer to a deficit in any of the processes, tasks, or functions related to cognition. To be considered an impairment, this deficit should be durable (as opposed to the temporary deficits caused, for example, by drug taking) and significant enough to effect daily functioning. Impairments may be mild, moderate, or severe, typically defined by the degree to which functional difficulties affect daily life. Rather than

being considered deficits or impairments, where compensatory strategies ensure that daily functioning is not significantly affected, it is more appropriate to use the term *neurodiversity*.

Cognitive impairments are apparent in a range of clinically defined disorders, including neurocognitive disorders and neurodevelopmental disorders. Neurocognitive disorders are those in which a decline in cognitive function is apparent as a result of illness or injury. This category includes the following:

- *Dementia*, which is an umbrella term for a number of conditions associated with a gradual decline in functions of memory and thinking at a greater rate than might be expected by age. The most common type of such condition is Alzheimer's disease.
- Traumatic brain injury, which can affect a range of executive functions, particularly when the injury occurs in childhood, while the brain is still developing, and when the prefrontal cortex is affected. Indeed, the impact of such an injury in early childhood may not be realized until mid-adolescence, when affected areas of the brain are called upon to develop higher order executive functions.

Neurodevelopmental disorders are characterized by specific or general developmental difficulties that emerge in childhood and affect day-to-day personal, social, and academic functioning. This category includes a range of conditions related to cognition, including the following:

- Intellectual or learning disability is defined by deficits in global intellectual performance (typically measured by IQ) and associated difficulties in adaptive behavior that significantly affect everyday tasks.
- Specific learning difficulties are associated with certain areas of functioning, with no correlation to global intellectual functioning. (Indeed other areas of functioning may be improved by way of compensating for the specific difficulty.) This includes dyslexia, which is associated with difficulties with literacy resulting from deficits in working memory and speed of processing, and dyspraxia, which can affect the ability to organize and execute novel tasks.

- Maternal consumption of alcohol during pregnancy can result in fetal alcohol spectrum disorder, which, in addition to physical manifestations, can affect intelligence, coordination, and behavior.
- Attention-deficit/hyperactivity disorder can include symptoms related to ease of distraction, short attention spans, deficits in working memory, and impaired executive control.
- Autism spectrum disorder is characterized by varying profiles of cognitive strengths and difficulties, including understanding of the perspectives and thoughts of others and regulation of behavior.

These varied examples demonstrate that young people with certain neurodevelopmental disorders may therefore not develop the cognitive skills normatively associated with specific ages or periods of development. In particular, assumptions of cognitive maturity in early adolescence—as defined by flexibility in thinking, complex reasoning, and problem-solving—may not be applicable.

Cognitive Impairments and Criminality

While there is some evidence associating emergent criminal behavior in older adults with the onset of dementia, it is the neurodevelopmental disorders of childhood that are of particular concern in considering the relationships between cognitive impairment and criminality. There is ever-growing research evidence of the overrepresentation of young people with cognitive impairments and related clinically defined disorders in the criminal justice system. This includes a disproportionate prevalence of neurodevelopmental disorders among young people within the youth justice system and in particular among those in custodial institutions. For example, estimates of the prevalence of intellectual disability in the youth justice system typically range from 25% to 33%, compared to 2–4% in the general youth population. It is also apparent that cognitive impairments are associated with *life course persistent*—as opposed to *adolescence-limited*—offending, that is, with offending that begins in childhood and is sustained into adulthood, beyond the typical age of desistence from such behavior in late adolescence/early adulthood.

Understanding the relationship between cognitive impairment and offending requires consideration to the direct influence of impairment on

functioning and behavior, to the indirect influence on other social experiences related to offending, and to the ineffective responses to impairment in many criminal justice systems.

Cognitive Deficits Increase Risk of Criminality

Specific cognitive deficits can directly influence propensity toward aggressive or antisocial behavior in particular contexts or social situations and therefore increase vulnerability toward criminality. This suggests that, while young people with cognitive deficits may commit crime for exactly the same reasons as other young people, there may also be certain additional triggers or particular patterns of behavior related to the impairment. For example:

- Deficits in executive control are known to influence certain forms of antisocial behavior by reducing inhibition and the ability to regulate behavior and by impeding the capacity to anticipate the consequences of particular actions. This is particularly apparent in emotionally charged or novel situations, reducing the capacity to recognize what is, and what is not, socially appropriate behavior.
- Similarly, difficulties with impulse control inhibit the ability to resist the temptation to gratify immediate desires, regardless of whether such behavior might impact negatively on the self or others, as in the case of criminal or antisocial behavior.
- *Cognitive empathy* refers to the ability to understand the perspectives of others and to foresee the impact of one's own behavior on them. In the context of antisocial behavior, this is apparent in understanding and responding to the feelings of one's potential victims. Deficits in cognitive empathy are associated with a range of relevant childhood disorders and conditions, including attention-deficit/hyperactivity disorder, traumatic brain injury, and intellectual disability.

Negative Social Experiences Further Increase Risk of Offending

The existence of such traits is, of course, not deterministic of offending behavior or criminality or

therefore sufficient explanation for the heightened risk of serious and persistent offending among those with cognitive impairments. Consideration must also be given to the parallel heightened susceptibility to social experiences that can lead to a greater risk of involvement in the criminal justice system.

Cognitive impairment can affect a range of known significant risk factors for offending, including family functioning and peer influence. This influence is most apparent in relation to experiences of educational disengagement. Cognitive impairments clearly inhibit learning. Young people with intellectual disability can experience deficits in memory and problem-solving skills, which inhibit academic performance. Similarly, those with specific learning difficulties may struggle to engage in school, where such difficulties are unrecognized or inadequately supported.

For many young people with cognitive impairments, difficulties apparent prior to starting school can inhibit school readiness. For example, a variety of symptoms associated with fetal alcohol spectrum disorder develop in the preschool phase, including impulse control, a short attention span, an inability to concentrate, and a poor memory. Early educational experiences can have a cumulative effect on educational careers. At the age of 8 years, a child is typically expected to have sufficient underpinning literacy skills so as to enable him or her to read to learn. Those children who have not developed sufficient skills may therefore find this transition particularly difficult. It is well demonstrated that it is at this age that problem behavior in the classroom can become more apparent. For many, this may therefore be a response to their difficulties in engaging with their learning. Similar risks of disengagement are also apparent in the transition from the more nurturing environment of primary school to the secondary school that places significant academic, organizational, and social demands on the student.

The influence of cognitive impairment on social and environment factors linked to the risk of criminality is also apparent among adults. In particular, those with cognitive impairments may not so readily experience factors known to be key to processes of desistance in young adulthood. For example, young adults with attention-deficit/hyperactivity disorder or intellectual disabilities have been found to be less likely to be engaged in

stable, long-term employment, while those who have experienced childhood traumatic brain injury are at greater risk of experiencing difficulties forming and sustaining serious romantic relationships.

The Criminalization of Cognitive Impairment

Such experiences reflect both the influence of impairment and the often inadequate response of services and support. Whether or not there is an accurate diagnosis determines how a person's needs are understood and responded to by a range of professionals, including in schools and in the workplace. This is equally apparent in the criminal justice system, with various practices serving to increase the inadvertent risk of criminalization of those with cognitive impairments.

Inadequate screening and assessment and staff training lead to poor recognition of impairment and therefore a failure to respond appropriately. Without such recognition, specialist services may not be made available, including appropriate support during police interviews or when giving evidence.

Specialist interventions to address offending behavior directly related to cognitive impairment are typically limited. Available generic interventions tend to assume normative levels of cognitive competence. For example, interventions in the youth justice system often seek to utilize metacognitive skills—that is, the ability to reflect on and alter one's own thinking processes—so as to understand and alter offending behaviors. Such approaches may therefore be inappropriate for some young people with cognitive impairments, leading to difficulties engaging with and effectively completing court orders.

People with particular cognitive impairments also struggle to effectively understand and engage with various criminal justice processes. For example, cognitive impairment can inhibit engagement in forensic interviews in the courtroom or police station, due to difficulties retelling a story, particularly when asked to do so in a fractured or non-chronological manner. Furthermore, without recognition of these underlying difficulties, an inability to answer questions may be perceived as willful noncompliance, an attempt to conceal details, or fabrication and lying. It is clearly

imperative to counter such discrimination so as to ensure capacity to engage in the legal process and offer an effective defense. Only by recognizing and responding to the specific needs of people with cognitive impairment can experiences of discrimination and criminalization be countered.

OFFENDERS WITH MENTAL DISORDERS: TREATMENT OUTCOME RESEARCH

Since the 1950s, deinstitutionalization of psychiatric hospitals and the tightening of involuntary commitment laws in the United States have made it very difficult to place someone into psychiatric care against his or her will. Therefore, many people with psychiatric disorders are now being dealt with in the community by the criminal justice system. Since the early 1990s, the Risk-Need-Responsivity model has been used to help the criminal justice system analyze offender risk of recidivism, determine the specific needs of the individual offender, and respond in a way that meets the offender's needs. Treatment outcome research is important, then, because it allows mental health-care providers to determine whether the responsivity is meeting the needs of the highest risk offenders. The entry begins with a discussion on mental health treatment outcome research for justice-involved individuals, including mentally disordered offenders. Then, there is a general discussion of what works and what does not work. Finally, characteristics of good outcome research are presented.

Treatment Outcomes

Some researchers have tried to research treatment outcomes by collectively examining many smaller research findings together (i.e., combining a number of smaller studies into one large study). This technique is referred to as a *meta-analysis*. Two key meta-analyses have been published since 2015 focusing on people with mental disorders who are in the criminal justice system. Both of these meta-analyses, one by Robert Morgan and colleagues and another by Isabel Yoon and colleagues, provide evidence that treatment is efficacious. Mental health treatment resulted in a better behavior, a reduction in anxiety and depression, and lower treatment costs incurred by the criminal justice system.

The first meta-analysis by Morgan and colleagues examined more than 12,000 documents from online databases. Using various standards,

26 studies were selected to be a part of the meta-analysis. These studies were conducted from 1973 to 2004. The final sample consisted of 1,224 people who completed treatment along with 260 offenders in control groups. Those who were included in the study were people involved in the criminal justice system who also had a serious mental illness, such as schizophrenia, mood disorder, or anxiety disorder.

Morgan and colleagues found that treatment groups fared better than control groups among a variety of outcomes of interest. First, treated offenders with mental illness reduced distress in general. Those treated were better able to deal with their problems and also better at adjusting to institutional rules. Treated offenders tended to have better behavior. When patients were given homework that focused on developing new behaviors and skills, treatment was more successful.

Another finding was that group therapy was effective with open groups as well as closed groups. An open treatment group means that as group members leave the treatment group, new members are added. A closed group means that when group members leave the treatment group, no new members are added. This is also an important finding for fiscal reasons, as open groups allow more offenders to gain access to therapeutic services in a timely fashion. This finding contradicted some clinicians' concerns that the addition of a new group member would disrupt (e.g., negatively impact trust, therapeutic rapport), rather than enhance, the group efficacy.

In a separate study, Morgan and colleagues found that individuals with serious mental illness who received a treatment program called *Changing Lives and Changing Outcomes* had a strong therapeutic alliance and were satisfied with the program. The study included 169 participants, both male (111) and female (58). Participants in the program had positive outcomes such as symptom reduction and evidence of reduced criminal thinking. Throughout the program, participants were required to take quizzes to measure their retention of course content. Those who retained the most information were more likely to complete the entire program, whereas those who retained the least amount of information were most likely to drop out of the program. The authors suggest that when a person is likely to

drop out, other modes of treatment such as individual treatment, peer tutors, or even behavioral reinforcement strategies to incentivize treatment continuation may be needed.

Another meta-analysis on treatment outcome research for mentally disordered offenders was conducted by Isabel Yoon and colleagues and published in 2017. This study examined 37 studies from 1979 to 2015 from several countries: China, India, Iran, Norway, Spain, the United States, and the United Kingdom. Participants had to be prisoners (not simply involved with the criminal justice system) who had been a part of randomized clinical trials. Participants were voluntary and had post-traumatic stress disorder, depression, or other psychiatric symptoms. The 37 studies included 2,761 participants.

Evidence from this meta-analysis revealed that cognitive behavioral therapy and mindfulness are useful theoretical approaches for improving symptoms of anxiety and depression. Randomized clinical trials, the gold standard of treatment outcome research, which focused on trauma-based treatment, however, showed little to no impact in reducing trauma symptoms in prisoners. One caveat to this finding is that prisoners may be experiencing a great deal of trauma inside prison as well as coming to prison with a history of traumatic experiences and thus trauma-related symptoms. It is possible, then, that trauma-based therapies are helping to reduce symptoms that are increasing naturally as the prisoner experiences prison life. Third, art and music therapy (action-oriented therapies) did not produce evidence that supported their efficacy. As mentioned earlier, these therapies may work for some, but there is little research about how well they work for prisoners. Finally, group therapy was found to be as successful as individual therapy when treating prisoners. This is important because group therapy can treat more people at once, thereby reducing the cost of treatment per prisoner.

Additional research by Jennifer Skeem reveals that specialty probation was much more successful than traditional probation for those with a mental illness. Skeem studied 359 probationers with mental illness for more than 7 years. Just over half ($n = 183$) of probationers received specialty probation while 179 received traditional probation. Specialty probation consisted of

smaller, homogenous groups and was focused on individualized treatment provided by experts. Rearrest rates reveal that those on traditional probation were 2.68 times more likely to be rearrested than those on specialty probation.

Discussion

Research conducted since the 1970s reveals that mental health treatment is efficacious for those with mental illnesses involved in the criminal justice system: Symptoms are reduced and behavior is better. This holds true if the treatment outcome research focus is on *offenders with mental disorders*, those incarcerated, and also those on probation. Treatment outcome research has also revealed the cost-effectiveness of treatment, particularly as it reduces rearrest rates.

Cognitive behavioral therapy helps to improve the symptoms of depression and anxiety. Cognitive behavioral therapy is enhanced by treatment that requires homework focused on developing new behaviors and skills. Those who retain content appear most likely to complete treatment. More research needs to be conducted on those who are most likely to drop out of the treatment program. Helping potential dropouts stay in the program should result in better outcomes.

Group therapy and open groups are as efficacious as individual therapy and closed groups. This leads to a reduction in therapeutic costs. Specialty probation as compared to traditional probation saves money as the probationer is much less likely to be rearrested. Future research should determine who is most likely to benefit from specialty probation and/or which aspects of the specialty probation is most beneficial.

Trauma-related symptoms, however, were not shown to be reduced by mental health treatment. Also, there is no evidence that action-based therapies such as art and music therapies are efficacious.

Past research has suffered from a number of methodological issues. There are some commonly agreed-upon characteristics of good outcome treatment research. Data sets need to be larger than that in the past whereby participants are randomly placed into therapeutic conditions. There needs to be more data collected on who drops out of the treatment groups. Self-report data are common in treatment outcome research but it would

be more desirable to have objective data on participants' behavior.

OFFENDERS WITH MENTAL ILLNESS

Offenders with mental illness are disproportionately represented in the criminal justice system. In fact, rates of mental illness among offenders far exceed that of the general population. Serious

mental illnesses among offenders include psychiatric diagnoses such as schizophrenia, bipolar disorder, depression, and anxiety disorders. Furthermore, offenders with serious mental illness have a co-occurring substance use disorder, known as a *dual diagnosis* or *concurrent disorder*, at higher rates compared to the general population. Some offenders also have psychiatric diagnoses, such as personality disorder or post-traumatic stress disorder, that are not equated with such severe functional impairment as schizophrenia, bipolar disorder, and depression but still create challenges for treatment and program management within correctional facilities (e.g., jails, prisons, detention centers).

Approximately 14–16% of offenders have a serious mental illness, although there is great variation of prevalence estimates across studies. In fact, it is believed that most rates underestimate the actual prevalence of offenders with mental illness, with some suggesting prevalence rates of 25% or higher. In addition, prevalence rates of mental illness are higher among female offenders compared to male offenders.

Offenders with serious mental illness differ widely in type of diagnosis and severity of symptoms related to their psychiatric diagnoses and can pose unique challenges within the correctional systems, which have become responsible for their supervision, treatment, and rehabilitation. Offenders with mental illness tend to have longer periods of incarceration, are less likely to be released on parole, and tend to have higher rates of reoffending compared to offenders without a mental illness. This entry focuses on the overrepresentation of offenders with mental illness within correctional facilities and discusses mental health screening, correctional treatment, and reintegration of offenders with mental illness.

Overrepresentation of Offenders With Mental Illness in Corrections

The overrepresentation of offenders with a mental illness has increased substantially over the years, with some suggesting that overrepresentation of mental illness in corrections has always been an issue. For example, many correctional facilities had high rates of offenders with a mental illness prior to the development of psychiatric hospitals.

The overrepresentation of offenders with mental illness in correctional facilities has been attributed to changes in the provision of psychiatric care and is believed to have resulted in the criminalization of persons with mental illness when combined with strained community-based mental health services. The most extreme change in provision of mental health care is known as *deinstitutionalization*. Deinstitutionalization refers to the movement of persons with mental illness from psychiatric hospitals into community-based mental health care. As a result of deinstitutionalization, drastic shifts in the provision of psychiatric care occurred, with many people being discharged from psychiatric hospitals into the community without homes or social supports.

The community-based mental health services that then became responsible for the care of persons with mental illness discharged from hospitals were not equipped to sustain the increase in demand for their services. A lack of available mental health services especially in terms of case management and outreach services put a strain on an already overtaxed community-based mental health system. As a result, individuals who may have been previously institutionalized were not receiving the mental health services they needed to function in the community.

The notion that persons with mental illness are funneled through the criminal justice system as a way to access psychiatric care has been provided as a rationale for the overrepresentation of offenders with mental illness within correctional facilities. Essentially, as a consequence of deinstitutionalization, people unable to access mental health services became involved in criminal activity, resulting in incarcerations, as a way to access mental health services.

Furthermore, social problems such as poverty, homelessness, substance abuse, and social marginalization; legal changes; and changes in mental health-care funding have also been contributing factors in the overrepresentation of persons with mental illness within correctional facilities. It is also believed that some criminogenic risk factors (e.g., antisocial cognition) are as common if not more common among offenders with mental illness, putting them at increased risk of involvement with the criminal justice system.

Thus, due to a growing number of individuals with mental illness living in the community, unaddressed social problems, legal changes, and a limited capacity to provide community mental health services, more individuals are being diverted from the mental health system into the criminal justice system.

Mental Health in Corrections

Correctional facilities were not designed to provide comprehensive mental health treatment and so face challenges in meeting the needs of offenders with mental illness. Furthermore, as the population of offenders with mental illness has grown, the requirements that these correctional facilities provide mental health treatment and interventions to this population have stretched their resources. To complicate matters, conditions within correctional facilities can further exacerbate mental health symptoms, and offenders with mental illness often struggle to manage the stresses and expectations correctional facilities place on them. Inmate safety is also a concern among offenders with mental illness, as these offenders have an increased risk of victimization and self-harming, so extra correctional staff resourcing may be required. Essentially, the increasing number of offenders with mental illness has substantially changed the landscape of mental health services within correctional facilities. Even so, with the right screening, resources, and provision of mental health services, offenders with mental illness can experience significant treatment gains during incarceration.

Screening and Assessment of Mental Illness Among Offenders in Correctional Facilities

Screening of mental illness among offenders provides a brief overview of psychiatric symptoms, behavioral concerns, and other information that is utilized to establish the presence of psychiatric and/or behavioral problems requiring treatment and intervention. Screening can inform the need for acute care treatment interventions to help stabilize an offender's mental health symptoms.

Mental health screening within correctional facilities is intended to identify psychiatric

elements of an offender's current level of risk, symptoms, and overall functioning. Specifically, the intake screening process examines acute care needs such as risk of harm to self or others, current mental health and substance use symptoms, and an offender's level of functional impairment. The screening process may involve interviews with offenders at intake into correctional facilities, use of self-report instruments, and/or review of clinical and correctional offender files. The results of mental health screening are used to determine the need for further psychiatric assessment.

Mental health assessments provide a more detailed and intensive overview of the psychiatric and behavioral problems, informing psychiatric diagnoses, treatment interventions, and intensity of treatment required. Specifically, assessments review the severity of mental health and substance use disorders, barriers to treatment, offender motivation toward treatment, and inform types and intensity levels of treatment interventions.

Along with assessment of mental health needs, correctional facilities also complete risk assessments on offenders with mental illness to establish which criminal justice risk factors to target in treatment interventions to reduce the risk of reoffending. Risk assessments also inform the level of security required for correctional supervision for offenders with mental illness.

Mental health screening and assessment are necessary to determine the appropriate type and intensity level of treatment interventions to best meet the needs of offenders with mental illness. The combination of screening and assessment of psychological and criminal risk is essential in correctional treatment among offenders with mental illness. Offenders with mental illness have been found to have improved outcomes as a result of intake screening and assessment of mental health and criminogenic needs. Criminogenic needs (e.g., substance abuse, antisocial attitudes, employment, family relationships) are factors that change over time (dynamic factors) and are considered part of a person's risk level that when changed through targeted treatment can reduce a person's likelihood of reoffending.

Correctional Treatment Interventions

Over the years, there have been many shifts in the way treatment of offenders with mental illness has

been provided within correctional facilities. Traditionally, the focus of treatment of offenders with mental illness was on providing access to care through psychiatric medications and treatment. Based on the influence of changes in psychiatric care, the focus shifted to incorporate the recovery model within psychiatric treatment interventions provided to offenders with mental illness. The recovery model emphasizes psychological treatment and rehabilitation that support the offender's return to pre-mental illness functioning. More recently, there has been a shift to address both mental health and criminal justice risk factors (criminogenic needs) within treatment to support overall recovery and reduce risk of reoffending among offenders with mental illness. Overall, mental health services in correctional facilities identify mental health needs, crisis management (e.g., risk of self-harm or suicide), and establish treatment interventions based on offenders' individual needs.

Initially, most treatment interventions for offenders with a mental illness within correctional facilities focused on providing access to mental health services through pharmacotherapy (i.e., the provision of psychiatric medications). Medication adherence among offenders with mental illness was associated with decreased psychiatric symptoms and decreased rates of psychiatric relapse. Pharmacotherapy was considered to be a primary mental health treatment for offenders' mental health symptoms and supported the premise that addressing offenders' mental health needs would in turn reduce their contact with the criminal justice system.

Although psychiatric medication is still a component of mental health treatment within corrections, treatment interventions have expanded to incorporate psychological interventions to support offenders' mental health recovery. The perception was that by targeting offenders' mental health needs within treatment interventions, criminal justice involvement among offenders with a mental illness would be reduced or eliminated.

Research has indicated that targeting only mental health needs in treatment interventions among offenders with mental illness improves clinical symptoms but does not reduce rates of reoffending among offenders with a mental illness. Evidence suggests that to reduce rates of reoffending

among offenders with mental illness, treatment interventions need to target criminogenic needs as well as mental health needs. Thus, a more holistic approach to treatment for offenders with mental illness targeting both mental health and criminal justice risk factors within treatment interventions has been suggested for addressing clinical symptoms and reducing the risk of rehospitalization and/or reincarceration among this offender population.

Essentially, the aim of correctional treatment and rehabilitation methods for offenders with mental illness is to reduce psychiatric symptoms, support psychosocial functioning, and improve subjective well-being, as well as reduce the risk of reoffending among offenders with a mental illness. This combined treatment approach, targeting both mental health and criminogenic needs, can reduce an offender's likelihood of psychiatric hospital readmission and return to the criminal justice system on new charges or revocation of parole upon release into the community.

Community Reintegration of Offenders With Mental Illness

To ensure that treatment effects and skills learned by offenders with mental illness can be applied in the community, correctional mental health treatment should connect with community reintegration efforts. Based on the high risk of rehospitalization and/or reincarceration among offenders with mental illness, research supports the notion of addressing the criminal justice risk factors along with mental health treatment needs within correctional treatment and ensuring that targeted treatment efforts are continued once the offender is released into the community.

Discharge plans, which are developed during an offender's incarceration, provide a detailed outline of the individual treatment and service needs of an offender. Discharge plans can inform the community treatment needs and prior to release can inform community-based mental health services to support continuity of care. The extent of discharge planning varies and is dependent on the offender's unique needs and the resources available within the community into which the offender is being released. Essentially, the combined mental health and criminal justice treatment interventions

support the offender's mental health recovery, reduce the risk of reoffending, support reintegration, and comprise a continued focus of treatment intervention once the offender is within the community.

OFFENDERS WITH MENTAL ILLNESS IN PRISONS, TREATMENT FOR

Rates of mental illness are higher among incarcerated populations than among community populations. Various explanations for this phenomenon have been discussed in the literature, with mental illnesses proposed as direct or indirect causes of criminal behavior, correlates of other factors associated with crime (e.g., community socioeconomic factors), or consequences of incarceration. Regardless of how persons with mental illnesses come to

reside within prisons, they present a number of challenges to criminal justice professionals charged with the provision of health care, the management of correctional institutions, and the protection of basic human rights. Generally speaking, mental health treatment refers to any intervention targeting problems of thought, emotion, or behavior. The unique characteristics of the prison environment influence mental health treatment in a number of ways, from the targets, structure, and content of interventions. This entry summarizes the extent of the mental health difficulties observed in prisons as well as justifications for, types of, and special considerations pertaining to mental health treatment offered to offenders with mental illness in prisons.

Rates of Mental Illness Among Incarcerated Offenders

Rates of mental illness among prison populations are difficult to estimate for a number of reasons. First, mental illness is a heterogeneous concept. In the same way that physical illnesses vary in symptoms and severity, from the transient effects of common viruses to the terminal consequences of various forms of cancer, mental illnesses vary in important ways. Some mental illnesses persist over weeks, while others persist over many years and even over a lifetime. Some mental illnesses are associated with increases in goal-directed behavior, while others are associated with a decrease in such behavior. Some mental illnesses are specific to a single aspect of the individual's experience (e.g., a phobia reflecting fear of a single object or experience), while others impact the individual across various domains of functioning (e.g., personality disorders). Thus, it is difficult to reduce these diverse illnesses into a single number. Second, the measurement and identification of mental illnesses within prison populations is often challenging. For instance, arriving at formal diagnoses using existing structured approaches, such as the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* and the *International Classification of Diseases and Related Health Problems, 10th Revision*, requires appropriately trained mental health professionals and can be costly and resource intensive. Even when professional resources make formal diagnostic

assessments feasible, correctional institutions may be interested in and impacted by mental health problems that do not fully meet strict diagnostic thresholds.

Nonetheless, empirical estimates of the rates of mental illness among prison populations are available. In 2006, the U.S. Department of Justice released a report containing estimated rates of mental illness among various prison populations. They found that 73% of females and 55% of males incarcerated in state prisons, 61% of females and 44% of males incarcerated in federal prisons, and 75% of females and 63% of males incarcerated in local jails experienced mental health problems. In Canada, the Office of the Correctional Investigator reported that 45% of federal offenders (i.e., offenders sentenced to a period of incarceration lasting 2 years or more) received some form of mental health intervention in 2011–2012. One Australian study from 2011 found that over 50% of police detainees had a history of involvement with the mental health system. Similarly, a study of prisoners in India in 2011 reported that approximately two thirds of the participants had a mental illness. Overall, this research indicates that mental illnesses are common among offenders in prisons internationally.

Why Treat Mental Illnesses in Prison?

For some readers, the justifications for providing incarcerated offenders with mental health treatment may not be immediately obvious. In many cases, mental health treatment is warranted to directly or indirectly support rehabilitative efforts to reduce risk of recidivism. For instance, individual offenders may receive mental health care to target a mental illness identified as a primary risk factor (e.g., an individual with crimes prompted by periods of acute psychosis), support participation in correctional or rehabilitative programming, or facilitate effective community functioning and reintegration. In addition, prison administrators may encourage mental health treatment to support the offender population's institutional functioning or security/operational activities. Beyond the criminogenic or correctional justifications for mental health treatment in prisons, offenders are also often considered to have rights to health care, including mental health care.

For instance, the Correctional Service of Canada is required by law to provide offenders in their custody with access to essential mental health services. In the United States, offenders with mental illness in prisons have a constitutional right to essential mental health care.

Types of Mental Health Treatment Offered in Prisons

Psychiatric Medication

Psychiatric medications are among the most common forms of mental health treatment offered to offenders with mental illness in prisons. These medications can be separated into many classes and are used to address a variety of mental health concerns. For instance, medication may be used to reduce acutely or chronically elevated anxiety, elevate or modulate problems with mood, improve attention and concentration, or reduce aggressive behavior. Offenders with psychotic disorders, which are characterized by hallucinations or delusions, may be prescribed antipsychotic medications. Individuals demonstrating difficulties with excessive or inappropriate sexual behaviors may be prescribed antilibidinal (i.e., sexual drive reducing) medications.

Psychological or Behavioral Interventions

Many mental health treatments offered to offenders with mental illness in prisons are primarily psychological or behavioral in nature. Many of these interventions are based on cognitive behavioral therapy (CBT) techniques. CBT interventions have received considerable empirical support and are used to address a number of psychological difficulties among offender and community populations alike. The CBT model posits reciprocal relationships among thoughts, emotions, and behaviors. As a result, CBT practitioners help clients to develop insight into and change their irrational or problematic cognitions, implement healthier behaviors, and regulate emotions. For instance, an offender presenting with impairments caused by excessive anxiety, such as avoidance of educational or exercise programming, may consistently interpret ambiguous information as evidence of negative social evaluation or danger. To assist this individual in overcoming

these impairments, a CBT practitioner might help the individual arrive at more balanced interpretations of events or plan behavioral experiments to test his or her assumptions about others' reactions to the individual. In addition to the large body of research supporting the effectiveness of CBT for common mental illnesses, such as anxiety and depressive disorders, there is now increasing empirical support for the application of CBT techniques to schizophrenia and other psychotic disorders.

Other mental health interventions offered in prisons are based on the relapse prevention approach, which was created to address alcohol and substance use problems. More specifically, this approach was developed to assist those individuals for whom positive developments made during treatment were not maintained after treatment. To develop a relapse prevention plan, the offender must identify risky situations in which problematic behaviors have occurred in the past or are likely to occur in the future. Once the offender has identified these high-risk situations, he or she then plans to employ alternative behaviors to navigate them more effectively. Research suggests that relapse prevention and CBT are both effective for reducing alcohol and substance use problems among offender populations and that they produce greater effects than punishment.

Many offenders with mental illness demonstrate deficits in social interaction or the completion of activities of daily living that are not unique to their particular diagnoses. As a result, behaviorally focused interventions targeting functional deficits in social and life skills are also employed among incarcerated offenders. Research suggests that these interventions can improve mental health as well as criminogenic factors.

Some incarcerated offenders demonstrate evidence of severe emotional and behavioral dysregulation. Dialectical behavior therapy (DBT) was developed as an intensive intervention for persons demonstrating such difficulties. DBT combines CBT principles with elements of mindfulness, emotion regulation, and distress tolerance skills. Research has indicated that DBT is effective for reducing a number of psychological and behavioral symptoms. For instance, DBT has been found to reduce the incidence of suicidal and self-injurious behavior among persons with

personality disorders. DBT programming has been employed at women's institutions operated by the Correctional Service of Canada, and an outcome evaluation identified improvements in both psychological and institutional functioning among the offenders receiving the treatment.

Special Treatment Considerations in the Correctional Environment

The nature of mental health treatment in prisons is influenced by unique aspects of the setting and the population being served. Consider, for example, the distribution of psychiatric medication. Prescribing professionals' decisions regarding medications are impacted by practical considerations pertaining to security, operations, and staffing. For instance, given that security staff may impose restrictions on institutional movement without warning based on security or safety considerations (i.e., blocking access to health care), professionals must consider whether to prescribe a fast-acting medication on an as-needed basis or rely on an alternative form of medication. In addition, service providers must be mindful of the reality that substance abuse difficulties are prevalent among prison populations, and various psychiatric medications have the potential to be abused. Beyond the individual patient, psychiatric medications may be exchanged as part of the illicit economy of goods and services operated by prison inmates.

Medication is not the only form of mental health treatment requiring special consideration in prison environments. Psychological service providers must also adapt their targets and methods to the realities of a prison. For instance, various treatments for anxiety or trauma-related disorders require graded exposure to real-world situations that may be impossible to re-create, or re-create safely, in a prison setting. Service providers also grapple with difficult questions such as, Who is the client? (e.g., the patient or the institution); What are the appropriate limits of confidentiality and privacy? and Is the offender's consent freely given?

Other special considerations apply to all forms of mental health treatment offered in prison. For instance, service providers must critically evaluate the extent to which their patients' self-report and presentation could be influenced by a desire for primary or secondary gains. An individual may

exaggerate or misrepresent symptoms to obtain medication, transfer to a more comfortable living arrangement, or mitigate the consequences of inappropriate behaviors.

Conclusions

Prisons contain large numbers of persons with mental illnesses. Mental health treatments may be offered in prisons to address diverse criminogenic or noncriminogenic needs. While community-based research and practice can inform the mental health treatment offered in prisons, treatments must also be adapted to the unique aspects of the prison environment.

OLDER VICTIMS OF CRIME

An increase in the proportion of the population that is considered older has led to growth in the number of older crime victims. Historically, older victims of crime have not received special attention; however, it is now recognized that the needs of older victims may be quite different from those of younger victims. Older victims may require assistance with transportation, special housing, financial counseling, personal physical care, or psychological counseling, for example. Having a sense of security and being able to live without fear for personal safety are also major concerns. This entry first discusses the older adults in general and then focuses on the needs of and services for older victims of crime.

The Older

The concept *age* can be easily measured since it is a continuous variable. To develop a better understanding of how age is related to an individual's development, emotions, and behavior during various periods of life, age has been conceptualized to include such categories as infant, young child, adolescence, middle age, and old age. These groupings are arbitrarily defined, and there is no agreement among researchers on the specific year that separates one category from another or on the specific year or age that should be used to define the *older adults*. Some researchers studying offenders and victims of crime categorize the *older adults* as age 60 years and older, whereas others choose age 65 years and older. The Federal Bureau of Investigation, in recording arrests made in the United States, categorizes older offenders arrested into groupings of 61–64, 65–70, and 71 and above. Research on victimization tends to follow the same categories as those used by the Federal Bureau of Investigation.

Trends in Size of the Older Population

An analysis of the trends in the population distribution of most economically developed countries of the world reveals that the proportion of the population that is considered older has increased during recent years, and this trend is expected to

continue. The percentage of the U.S. population defined as 65 years of age or older was about 13% in 2009. It is estimated that, by 2030, 71.1 million persons in the United States, or about 19% of the population, will be in this age group. It is predicted that by 2025, more than 62 million Americans will be aged 65 or older and 7.4 million will be aged 85 or older.

In addition, as a result of improvements in health care, communications, and education, changes in life styles (including types of employment), and changes in social relationships, the life span of the populations of most countries of the world has increased. People are living longer, working longer, and have more formal and informal contact with people outside their primary social relationships. In the past, a large proportion of the victimization of the older adults was by family members, relatives, and close acquaintances. However, the victimization of the older adults by non-primary group contacts has increased as a result of the aforementioned factors.

Older Victims of Crime

Older persons have become more vulnerable to criminal victimization for a number of reasons. A larger proportion of the older adults than in the past lives in nursing homes or managed care facilities, under the care of persons other than family members or relatives. If they remain in their homes, they may not have interaction with or emotional support from close family members. For those who are physically or mentally disabled, the need to rely on *outsiders* is more apparent. When family members are involved in older adult care, they sometimes abuse or steal from the older adults.

Researchers have identified such abuse as including neglect, emotional/psychological abuse, financial/material exploitation, and physical abuse. Researchers report that many older violent crime victims reported being victimized at or near their homes. Only about half of the older victims reported the victimization. Higher rates of victimization have been found for individuals who are living in low-income households, are unemployed or retired, are in poor health, have experienced prior traumatic experiences, and have low levels of social support.

The older adults often are the targets of fraud or scams. Such fraud and scams perpetrated against older persons include health care, Medicare, and health insurance fraud; counterfeiting prescription drugs; and fraudulent antiaging products. Other victimizations involve telemarketing scams such as the *The Pigeon Drop*, *The Fake Accident Play*, and *Charity Scams* as well as Internet fraud and e-mail phishing scams. Investment schemes, homeowner/reverse mortgage scams, and sweepstakes and lottery scams may also target older persons.

Response to Older Victimization

Much of the crime against the older adults is either not discovered by the victims or, whether detected by them, never reported to a person or agency that can provide assistance. The older adults in hospitals or nursing homes or under the care of their children often are not mentally capable of realizing that they are being victimized, as they may be too trusting of their caregivers. Moreover, they may be afraid of accusing their children, relatives, or other persons caring for them of wrongdoing. Those who are aware that they have been victims of fraud or scams may not report the victimization for various reasons, including the embarrassment of admitting that they have been tricked.

Crime Prevention Strategies for the Older Adults

The following are strategies known to be employed to prevent victimization of the older adults and to assist those who have been victimized:

- a communications network to keep the older adults alert to potential crime;
- information and training on how to report crime;
- services to support older victims in dealing with the physical, emotional, and financial impacts of crime; and
- access to products, training, and other services to help prevent victimization.

When employing such strategies, it is important that the information provided be factual and

truthful but not create such a fear of crime that the older adults are afraid to leave their homes to shop, go to church, or engage in social activities. To the extent possible, the older adults should be encouraged to engage in social interaction with family, friends, and others in the community.

Action strategies for preventing victimization of the older adults consist of legislation, providing services, and law enforcement programs. The Victims of Crime Act passed by the U.S. Congress in 1984 established the Crime Victims Fund. The funds are used to support victim assistance and compensation programs. All victims, regardless of their age, who have experienced physical or material harm from a criminal act can apply for assistance and compensation.

Crime Victim Assistance Agencies

Older victims of crime tend to rely on their family and friends for emotional and physical support. A secondary source of support is a victim service agency. These agencies provide such services as assisting the victim through the court system, providing assistance in crisis intervention situations, assisting the victim with the completion of forms such as requests for compensation, assisting with the completion of impact statements, and visiting victims at their homes. These agencies may also provide educational materials for crime prevention programs and training in personal safety. In addition, they may assist victims in locating housing and funds should they have immediate needs relating to food and shelter as well as make referrals to other agencies, including counseling agencies.

In many police jurisdictions, the security needs of the older adults have been recognized, and programs to ensure the safety of older citizens have been developed. These programs include the assignment of police officers to housing complexes for older residents, providing crime prevention education for the older adults, and establishing community policing programs in neighborhoods where the large majority of the residents are senior citizens.

ONTARIO DOMESTIC ASSAULT RISK ASSESSMENT (ODARA)

The ODARA is an actuarial instrument for evaluating risk of intimate partner violence (IPV). It is used to identify men at risk of violent recidivism; that is, a new offense of assault among men who have already committed an act of IPV. The ODARA is scored based on events at or prior to the most recent occurrence of IPV (the index assault). This entry describes how the ODARA was developed and validated, its use within a two-level assessment approach, and its application to other research questions.

Development and Validation

The ODARA was the first IPV risk assessment to be empirically developed. That is, component items were selected through statistical analysis in a follow-up study of offenders. The construction research included 589 men with a police report of assault on a current or former cohabiting partner and used information contained in police and criminal records to identify offender characteristics and circumstances that best distinguished men

who had a subsequent record of IPV from those who did not. Multivariate analyses were used to identify unique predictors, and the statistical sampling technique of bootstrapping was used to maximize the likelihood that the results would generalize to new samples. This empirical method makes it possible to develop assessment norms.

The ODARA contains 13 items, each scored 1 for yes and 0 for no based on explicit scoring criteria. In summary form, the items are as follows: pre-index domestic assault in police or criminal records, pre-index nondomestic assault in police or criminal records, pre-index sentence to 30 or more days in custody, failure on pre-index conditional release, threat to physically harm or kill anyone at the index assault, confinement of the partner–victim at the index assault, partner’s concern about future domestic assaults, more than one child of the offender or victim, victim having a biological child with a former partner, pre-index assault on the victim while she was pregnant, offender substance abuse, and barriers to victim support. The total score is the sum of the item scores, prorated where necessary for items treated as missing.

Actuarial tables for the ODARA show normative data for total scores. One piece of data is the likelihood of IPV recidivism, defined as a new record of assault on a cohabiting partner in the follow-up that averaged almost 5 years. This information depends on the definitions and time frames used in the original research and will not necessarily *calibrate* or generalize to other samples. The table also shows rank order in terms of the percentage of offenders at or below each score. These percentiles can be more informative as they allow individual offenders to be compared with other offenders in terms of their risk of IPV recidivism, regardless of its definition or absolute probability. The use of actuarial data to evaluate individual risk is considered controversial by some, but the predictive validity of this method is well established for both violence risk and general offending, and the numeric information that is yielded by actuarial assessment has been seen to improve violence risk communication.

Reliability and Validity

Interrater reliability of ODARA scoring among researchers and police officers has been excellent ($\geq .90$). The ODARA’s ability to discriminate

between subsequent recidivists and nonrecidivists has been demonstrated among men with or without a correctional history, presentenced offenders, and incarcerated men and women. Some research has validated the ODARA as a predictor of general violent and criminal recidivism and domestic sexual recidivism, among other outcomes. ODARA scores are also associated with the timing, frequency, and severity of subsequent IPV. In meta-analytic research, the ODARA compares favorably with other leading IPV risk assessments.

ODARA and Domestic Violence Risk Appraisal Guide

A two-level risk assessment process has been conceived in which the ODARA is used as a brief frontline tool, and the Domestic Violence Risk Appraisal Guide (DVRAG) is used where more in-depth assessment is possible and desirable. The DVRAG was developed as a result of research examining information not normally available to police for their ability to improve on the ODARA's predictive accuracy. Existing assessments were tested for their incremental value, and the Hare Psychopathy Checklist–Revised was the most consistent contributor to the empirical models of dichotomous and continuous measures of IPV recidivism, including severity and injury. An algorithm was derived for weighting Psychopathy Checklist–Revised score and ODARA items to construct the DVRAG. It is recommended that the DVRAG be used whenever the ODARA score is 2 or more, and a reliable Psychopathy Checklist–Revised score can be obtained.

Other Applications of the ODARA

ODARA score has been associated with IPV recidivism by female offenders, although women reoffend at a lower rate than men. As a result, the ODARA can be used to rank order female offenders with respect to their risk of IPV recidivism, but further research is necessary to obtain normative data regarding the absolute probability of reoffending among female offenders.

Emerging research indicates that ODARA scores are higher among male IPV offenders with co-occurring violence against children. A relevant ODARA item is the partner having biological

children with a former partner, which is a key risk factor for child abuse.

The ODARA has been used to evaluate the effect of policing intervention on IPV controlling for pre-arrest risk. A benefit of arrest was detected among lower risk cases, in that recidivism was delayed.

ORGANIZED CRIME ACTIVITIES

Organized crime activities is a broad term used to describe a variety of illegal activities often associated with criminal networks, groups, or organizations. A defining characteristic of organized crime groups is that they are profit-driven, supplying public demands for services and goods that are prohibited, regulated, cost prohibitive, or in short

supply. The potential list of criminal activities that organized crime groups are engaged in around the world is rather extensive. These activities include, but are not limited to, illegal gambling, extortion, labor racketeering, prostitution, money laundering, corruption, and the trafficking of humans, human organs and body parts, illicit drugs, weapons, stolen vehicles and parts, exotic animals, natural resources, and hazardous waste. To maintain their market share of illicit enterprises, criminal groups will resort to the use or threat of violence and will corrupt government officials in an attempt to avoid arrest and prosecution. Therefore, while the list of potential organized crime activities is extensive, these activities can be grouped into three broad categories: the provision of illicit goods, the provision of illicit services, and the infiltration of government and business.

Provision of Illicit Goods

Organized crime groups provide illicit goods to consumers around the world. The types of goods include illicit drugs, weapons, humans, human organs and body parts, exotic animals, stolen vehicles and parts, minerals and natural resources, art and antiquities, and a variety of counterfeited products. Markets for these goods emerge from legislation prohibiting or regulating the products, such as drugs and weapons, and others emerge because the products, such as designer or luxury items, are demanded for their status value but may be cost prohibitive. While the list of goods provided is extensive, the most common are illicit drugs, humans, weapons, and counterfeited products.

Illicit Drugs

The largest and most profitable commodity organized crime groups are responsible for is supplying illegal drugs. Criminal organizations around the world traffic marijuana, heroin, cocaine, methamphetamine, ecstasy, and synthetic drugs. The United Nations estimates the profits from the global drug trade at over \$300 billion annually, with the majority of these drugs destined for the United States and Europe. Most of the drugs trafficked into the United States transit the country's land border with Mexico. This has caused several drug trafficking organizations in

Mexico to emerge and compete for control over U.S. drug routes. In Europe, some drugs—namely cocaine—are trafficked from Latin America, usually transiting northwest Africa. Europe's heroin market, however, is supplied from Afghanistan. The United Nations estimates that Afghanistan supplies 90% of the world's heroin, though much of the heroin entering the United States comes from Mexico.

Humans

Human trafficking is the movement of people across state or national borders under fraudulent pretensions or coercion. Some organized crime groups are engaged in some aspects of human trafficking, supplying the sex industry with forced prostitutes, and legitimate businesses with cheap labor. Human trafficking is most often conducted by small criminal networks linked by familial and friendship bonds, as opposed to being controlled by criminal syndicates. Human trafficking sometimes starts as human smuggling, wherein smugglers/traffickers may take advantage of a political or economic crisis in one part of the world by offering to smuggle migrants from these nations to a destination country but later coerce them into the sex industry or into work with little or no pay. It is estimated that worldwide these activities involve millions of victims, although precise numbers are difficult to obtain.

Weapons

Organized crime groups are engaged in the acquisition, sale, and movement of both illegal and legal firearms. Criminal organizations acquire firearms on the black market or through the use of straw purchasers, who legally purchase weapons for the criminal organization. Mexican drug trafficking organizations, for instance, have acquired automatic assault rifles and other deadly weapons from the United States by using straw purchasers to buy firearms at gun shows and other venues. Approximately 90% of the guns recovered in Mexico can be traced to the United States. Other criminal organizations in Eurasia took advantage of unsecured weapons' stockpiles immediately following the collapse of the Soviet Union and sold these weapons on the black market in the Middle

East and Africa. To date, the black market in weapons is largely supplied by weapons manufactured in the United States, Russia, and China.

Counterfeit Products

Counterfeit products are products that are sold under another's brand name without the brand name owner's authorization. Many of these products are in high demand because of their perceived status but are too expensive for the average consumer. This situation creates a market for counterfeited products that are more affordable, though the quality of the product is often inferior to the legitimate version. These products include counterfeited purses, sneakers, cigarettes, T-shirts, medications, DVDs, CDs, and a host of other items. Since counterfeiting manufactured goods requires some level of organization, organized crime groups often have the connections and infrastructure to facilitate their manufacture, transportation, and distribution. Chinese Triads in Hong Kong—in collusion with businessmen and state actors—and other Asian organized crime groups are believed to be extensively involved in the manufacturing and trafficking of counterfeited goods.

Provision of Illicit Services

Like illegal goods, there is a demand for certain services that are prohibited or regulated, such as prostitution and gambling. Prostitution, for instance, has a history of being prohibited in the United States and in many other nations—but ironically in the context of a high customer demand for paid sex. Other services in demand, such as protection and dispute resolution, emerge from customers' participation in black market economies. Participants in illegal businesses, for example, cannot seek legal recourse to settle disputes, giving rise to the demand for dispute resolution and protective services.

Prostitution

Prostitution—or pay for sex—is one of the oldest vices in the world. In most nations, prostitution is illegal, although some have decriminalized it, deciding to regulate the industry instead. In the

United States, prostitution is mostly illegal, with the exception of the state of Nevada. While the true scope of sex services is unknown, estimates suggest that there are over 13 million prostitutes worldwide. China, India, and the United States, respectively, are estimated to have the largest number. These prostitutes often ply their trade in a number of different settings, including the street, brothels, massage parlors, and strip clubs. Organized crime groups often own or partially own these venues or, at a minimum, *tax* them in exchange for protection from law enforcement or from other criminal organizations seeking to extort them.

Gambling

Gambling, like prostitution, is a vice that has a history of being prohibited and/or regulated unevenly across and within countries. In the United States, for instance, some gambling is legal in certain states, such as Nevada and Connecticut. In addition, state-ran lotteries are legal; in certain coastal states, such as Mississippi and Maryland, offshore gambling ships provide customers with an opportunity to gamble in international waters. Despite circumscribed legislation legalizing gambling, organized crime groups continue to be involved in various ways. These include bookmaking (i.e., betting on the outcome of a sporting event), numbers rackets (i.e., a form of lottery, in which people place bets on a group of numbers), and video poker games. In addition, more recently, the American mafia has become involved in Internet gambling operations.

Dispute Resolution and Protection

Organized crime groups provide dispute resolution and protection to both legal and illegal businesses. These are services that larger and more structured criminal organizations with a reputation for violence and corrupt networks, like the American mafia, provide smaller, less well-organized criminal groups or legitimate businesses needing protection from extortionate demands from other organized crime groups. While some academics suggest the ability to provide protection is a unique characteristic of mafias—as distinguished from other forms of

organized crime—there are instances of prostitution rings operating in the United States that receive protection from violent street gangs. These larger criminal organizations often demand a street *tax* for their services, which can blur the line between these services and the offense of extortion (more on extortion in the next section).

Infiltration of Government and Business

Organized crime groups have an interest in nullifying the state in order to continue their illicit activities and generate significant revenue with impunity. To avoid or prevent state intervention, organized crime groups will corrupt government officials, use financial institutions to obfuscate illicit proceeds, establish front companies, or take control of legitimate businesses, and, with more sophisticated organized crime groups, control labor unions and pension funds. Organized crime groups, however, do not want the responsibility of running the day-to-day operations of legitimate businesses or government. Such groups will establish front companies or take control of a business to provide organized crime members with a means to launder illicit proceeds and to have a legitimate source of reportable wages for income tax purposes.

Money Laundering

Money laundering is the process of making illegally-gained proceeds appear legitimate. The offense typically involves three phases: placement, layering, and integration. Placement occurs when cash is converted to a monetary instrument or is deposited in a financial institution. Layering involves the movement of the placed money to other financial institutions to obscure its origin. Integration involves the use of the money to purchase legitimate assets or fund further activities. This process of making illegally gained proceeds appear legitimate is essential for organized crime groups. These groups want to make substantial profits from their illegal activities, but they must balance making such profits with avoiding undue attention from law enforcement by making their illicit proceeds appear to come from a legitimate source.

Corruption

Organized crime groups corrupt government officials at all levels—local, state, and federal—in an effort to conduct their illegal operations with impunity. Criminal organizations have corrupted local, state, and federal law enforcement officials, including customs and border patrol agents, politicians, judges, and other government officials. Corruption often occurs when an organized crime group offers a public official money in exchange for ensuring their criminal activity is not prevented, mitigated, or disrupted. These exchanges are possible because many civil servants throughout the world are not paid very well, and when faced with the prospects of receiving a significant financial payoff from a criminal group, they are willing to turn a blind eye to the illegal activity. A more subtle way organized crime groups corrupt politicians is through campaign financing or ensuring votes during an election year.

Extortion

Extortion is the acquisition of money or property under the threat of physical harm or damage to property. Organized crime groups threaten individuals and their loved ones or businesses with physical harm or damage. To avoid the harm, the victim is forced to provide the crime group with money or property. Italian, Eurasian, and Asian organized crime groups have been able to infiltrate legitimate businesses by initially extorting owners of small businesses, such as pizza parlors, cafes, bars, and other venues. The financial demands made on the legitimate business by organized crime groups are often exorbitant, and the business owner is unable to make continued payments. This leads to the crime group eventually proposing to become partial owners of the business. However, in some situations, a legitimate business may actually seek out the services of an organized crime group for protection and/or for a favorable business deal. This arrangement can, however, eventually turn into extortion when the business is unable or unwilling to continue to pay the organized crime group the *tax* they levy on their services.

Labor Racketeering

Labor racketeering is the infiltration of a labor union, employee benefits plan, or control over the labor workforce. More sophisticated organized crime groups have been able to penetrate labor unions and control employee pension funds. The American mafia, in particular, was able to infiltrate the International Brotherhood of Teamsters, the Laborers International Union of North America, the Hotel Employees and Restaurant Employees International Union, and the International Longshoremen's Association. This mafia was able to take control of these major national unions, and many locals, through the corruption of union officials. Through its control of these organizations, the mafia was able to steal from the unions' employee pension funds. These funds were then used to fund additional ventures, including casinos in Las Vegas, Nevada, for example.

In sum, the activities of organized crime constitute a set of illegal businesses. As with any business, the ultimate goal is not to espouse an ideology or even to gain power for its own sake but rather to make money—and as much as possible.

similarities and differences between two general types of organized crime groups in the United States: traditional Sicilian organized crime groups (referred to as “The Mafia” or *La Cosa Nostra*) and newly emerging groups. The entry concludes with remarks about the projected futures of these general types of organized crime groups operating in the United States.

Establishment of Organized Crime in the United States

To many people, the term *organized crime* conjures an image fostered by Hollywood as a gang of Italian mobsters dealing in the illegal alcohol of Prohibition, prostitution, gambling, and drugs. While the Sicilian gangs may have been the largest, most prominent, and well-structured ethnically based gangs in the history of U.S. organized crime, they were not the only gangs established on culture and nationality to enter the underworld nor were they even the first. Irish, German, and Jewish gangs had already left their marks when the Volstead Act (the National Prohibition Act) was passed in 1919 to enforce the Eighteenth Amendment to the U.S. Constitution, which banned the manufacture, distribution, and sale of alcohol, providing a new illegal product for gangs to serve to the buying public.

As World War II and the Cold War ended, U.S. society became more diverse with new ethnic groups from the former Soviet Union and Yugoslavia as well as countries of Latin America, the Middle East, Asia, and Africa arriving in the pursuit of the American Dream. Their reasons for immigrating to the United States were many and included a desire to escape the ravages of war and its aftermath, to escape various forms of religious and political oppression and persecution, to escape the limits of opportunity associated with the more caste-like societies of their homelands, and to partake of the American Dream of upward mobility through the fruits of their own independence and hard work. However, a very small percentage of the members of these groups chose to follow the model built by the traditional Sicilian mobsters who had arrived in the United States in the late 19th century and early 20th century seeking their fortunes in less conventional methods.

ORGANIZED CRIME TYPOLOGIES

Many authors have explained the concept of organized crime through various characteristics. After reviewing how organized crime became established in the United States, this entry describes the

The usual pattern featured the small criminal element perpetrating extortion on fellow immigrants. This extortion was usually rationalized as *protection*. In many instances, the new immigrants did not know the language or customs of their new country and did not go to the police because they often came from lands where law enforcement agents were feared and not to be trusted. In short, they assumed that the illegal acts of a very small number were to be dismissed as business as usual. Once these gangs became established and organized, they were free to expand into other illegal activities as the criminal market would dictate.

Characteristics of Organized Crime Groups

This section explores the characteristics that authors have used to describe organized crime groups. These defining characteristics are based on the similarities and differences between traditional Sicilian organized crime groups and newly emerging groups.

Absence of Political Goals

Organized crime activities are motivated solely on the basis of obtaining money and power and not by social doctrine, political beliefs, or ideological concerns. In most instances, organized crime groups do not want to change the existing political structure. To do so may remove their *raison d'être* or “reason for existence”—that is, to provide goods and services that are inherently illegal or too expensive to possess legitimately.

However, because organized crime groups have generally not adhered to any moral or ethical constraints on the activities pursued to obtain the money and power being sought, the cash flow of many of their business interests from the sale of raw materials for illegal drugs, human trafficking, and extortion has often been intertwined with stolen military equipment, including weapons and ammunition, by terrorist groups such as Al-Qaeda, the Taliban, and the Islamic State of Iraq and Syria. The members of both traditional and newly emerging groups justify their behavior as *just business*.

Hierarchical Structure

Traditional organized crime groups follow a vertical power structure with at least three permanent levels, while newly emerging groups tend to have a smaller and flatter organization chart. This structural difference is most likely due to the fact that new groups tend to focus only on one activity, usually drug trafficking. However, as the more established Sicilian groups matured after the era of Prohibition, they diversified into other areas of illegal businesses merely to survive. In some cases, they went back to their usual sources of revenue such as gambling, prostitution, and stolen merchandise but with expanded operations. They also ventured into new areas such as loan sharking and union infiltration. Importantly, they recognized the importance of money laundering to avoid the allegations of tax evasion. As a result, additional layers and compartments were needed to supervise and coordinate the activities more effectively and efficiently.

Limited or Exclusive Membership

With extremely rare exceptions such as Russian Meyer Lansky being associated with Sicilian Lucky Luciano's gang, organized crime groups limit membership to the gang on the basis of nationality and ethnicity. This characteristic is practiced by both traditional and newly emerging groups. It does not imply that all members of any particular ethnic group are criminal or that they even support organized criminal activity. Instead, what is meant is that the members of any organized criminal enterprise will not accept anyone from outside the ethnic group for full membership. In some cases, an organized crime group may be so selective that prospective members must come from a specific town or province within the parent country before any offer of membership is extended. For security reasons, members of a gang may be required to converse among themselves in their native tongue and dialect when discussing business.

Unique Subculture

Members of organized crime groups view themselves as different from conventional society and thus exempt from its rules. While the

two general categories of organized crime groups—traditional and newly emerging groups—view themselves as different from conventional society, members of established traditional groups at least make an effort to appear legitimate and respectable. In many cases, the businesses obtained for money laundering not only provide the appearance of legitimacy but also provide a base of operations for further criminal activity. During the 1950s, the Cantalupo Realty Company in New York City was such a company. Other traditional mobsters, most of whom came to power long after the repeal of Prohibition in 1933, participate in normal societal activities through churches and civic groups. For example, Frank Costello, who controlled the Luciano crime family after Lucky Luciano was imprisoned in 1936, was often seen displaying his flowers at various horticultural shows in New York. Today, many traditional organized crime gangs are staffed and led by the grandsons of the original bosses. They have taken great pains to avoid publicity and to blend in with normal society. In contrast, new groups have not yet learned to diversify beyond the illegal drug and at least appear to merge with mainstream society.

Self-Perpetuating

Members of an organized crime group operate under the assumption that the organization will continue beyond the human lives of the constituents. The first and second generations of traditional groups have also recognized the importance of cultivating successors from within their own biological families. They have sent their children to leading colleges and universities to learn how to run the criminal organizations as legitimate businesses. However, newly emerging groups appear to be concerned more with immediate results and to have not yet matured into a realization that for an organization to prosper in the long term, its leadership must cultivate trusted and loyal successors.

Willingness to Use Illegal Violence

For organized crime groups, the use of force, up to and including homicide, is not viewed in moral or legal terms but solely as a practical means to eliminate competition, settle territorial disputes,

provide an object lesson for witnesses or victims, or instill discipline within the ranks of the organization. Rival Sicilian gangs of the 1930s recognized after the repeal of Prohibition that to be most effective and to avoid public disapproval, any use of violence must be kept to a minimum and away from the public view. Above all, violence cannot turn innocent bystanders into victims. As long as the gang members quietly killed only each other and in a manner that did not draw attention, the public appeared to be tolerant.

Newly emerging groups, especially from the Russian mob and Latin American drug cartels, are far from discrete in their use of violence. Intended deaths of spouses, children, and neighbors of rival gangs are common. At the least, they are regarded as collateral damage, and at the worst, they are meant to be object lessons for the competition. Even completely innocent bystanders who happen to be at the scene of a gangland murder are considered to be unwanted nuisances and potential witnesses.

Monopolistic

While competition is usually viewed as the motivation for improving quality and efficiency in capitalist society, it is avoided in organized crime. Among traditional organized crime groups, a monopoly is generally achieved by the subtle corruption of politicians and police personnel who can eliminate or control any competing groups. Newly emerging groups prefer to use force and intimidation as their methods of directly obtaining and maintaining their territorial monopolies.

Governed by Rules and Regulations

Like any other business, an organized crime group expects its members to adhere to a set of rules and regulations. Unlike a legitimate establishment whereby a violation of rules can result in demotion or termination of employment, violation of the criminal gang's rules and regulations often involves the death of the violator. Traditional organized crime groups follow strict rules for everything from etiquette during meals to the manners displayed in front of the children and spouses of rivals. Newly emerging groups do not recognize such rules.

Future of Organized Crime Groups

Newly emerging organized crime groups may share many similarities with traditional groups, but the differences are more numerous. These differences tend to produce a perspective by the public that the new groups are more violent, more odious to society, and more malevolent in the goods and services that they provide. Consequently, society is thought to be less indulgent and forgiving than it was toward traditional gangs. The new gangs are not more criminal than their predecessors nor are they more intrinsically malicious or immoral. They simply do not stay absent from the public eye. As far as the public regards traditional organized crime groups, the adage that *out of sight, out of mind* rings true. As newly emerging organized crime groups go through a maturation process, their activities will continue, but they will likely gradually become less obvious.

Organized crime is a consumer-driven phenomenon. Whether the product is the illegal alcohol of Prohibition, stolen goods, dangerous drugs, gambling, or any of the other myriad ways that the groups have seen a potential for profit, it is the customer who generates the demand. Even when a product is entirely legal but unattainable through limited supply or an excessive price, it is the organized crime groups that can satisfy the demand. Prohibition did not stem the desire to consume alcohol by making the production, distribution, and sale illegal. Knowing the dangers and consequences had little effect on the public's appetite. Prohibition merely slowed the flow at best; at worst, it resulted in disregard and contempt within the public for the criminal justice system.

Finally, the lure of pursuing the American Dream has attracted many people to the United States. The overwhelming majority of new arrivals has conformed to the legitimate model of hard work in the classroom and workplace, patience,

perseverance, honesty, and ethical behavior in the free market. However, a small percentage has still desired the goals of upward mobility, financial independence, and freedom of choice but has elected to find alternative means to achieve these ambitious ends.

Regardless of the ethnicity of an organized crime group developing from the attraction of these goals, after establishing itself with various forms of extortion rackets that victimize its own fellow immigrants, the group will then conduct its own form of a market survey to determine what illegal goods and services will be most profitable for its continued operations.

P

PAROLE

Parole is defined as a period of conditional supervision within the community following release from a prison term. This is in contrast to probation, which also includes conditional supervision within the community but typically serves as an alternative to incarceration. In other words, parole involves community supervision after serving a prison sentence, whereas probation involves community supervision as the sentence instead of prison. In the majority of jurisdictions within the United States, parole supervision agencies are housed within state correctional departments while in others they are separate, independent entities. There are two general forms of inmate release to parole: discretionary parole release by a parole board or mandatory parole release.

All offenders are provided with certain provisions that they must follow while on parole supervision. If an offender violates these conditions, then parole may be revoked and the offender may be sent back to a correctional institution to serve the remainder of the sentence. Parole revocations are not uncommon, and most revocations occur shortly after an offender's release from prison. There are many issues faced by parolees when reintegrating into society, which contribute to the high rate of returns to prison, including disconnection from family and friends, substance abuse, homelessness, and unemployment. Research

exploring the effectiveness of parole supervision in reducing recidivism is mixed.

Current Parole Estimates

The majority of parole supervision agencies in the United States are located within state correctional departments. Thirty-eight states have a joined probation/parole/corrections agency. Many jurisdictions supervise both probation and parole populations within one agency, while 17 states do not. Five states—California, Texas, Illinois, Pennsylvania, and New York—supervise nearly half of the nation's parole population.

In 2014, there were more than 4.7 million adults under community supervision in the United States, and 18% of this population (or nearly 857,000 persons) were on parole supervision. Although community supervision rates overall have declined in recent years, the adult parole population increased by 3.7% from 2007 to 2014. In addition, the average amount of time offenders remain on parole supervision increased from nearly 18 months in 2010 to approximately 23 months in 2014.

The majority of parolees under community supervision are male (88%). Recent estimates from the Bureau of Justice Statistics show that 43% of parolees are White, 39% are Black, and 16% are Hispanic. Approximately 56% are on parole supervision for a felony offense; the most common types of offenses committed by offenders placed on parole include property and drug offenses.

Parole Release

Discretionary Parole Release

In some states, parole is granted on a discretionary basis by a parole board. A parole board is a group of individuals (usually appointed) who review inmate cases to determine whether an offender has been sufficiently rehabilitated while incarcerated and will successfully reintegrate into the community upon release. In states where discretionary parole is practiced, parole boards have four primary functions: to place inmates on parole, to supervise parolees in the community, to discharge parolees from parole, and to determine whether parole should be revoked if the parolee has violated the conditions of parole.

Depending on the jurisdiction, parole is granted at a parole hearing or a series of parole considerations. During this process, the board reviews the inmate's information and may meet face-to-face with the offender. This provides inmates who are being considered for parole with an opportunity to present their side of the offense and explain why they believe that discharge on parole supervision is deserved. The offender's accomplishments while incarcerated are discussed, and the inmate's plans for housing and employment after release are reviewed. Victims' statements may also be reviewed by the parole board. The main goal of the parole hearing is to determine any problems that an offender has had in the past and those issues that he or she may face in the future once released. Thus, the board takes into consideration both the needs of the offender and any potential public safety concerns when making a parole decision. Parole is granted to the offender if the board believes that the parolee will successfully reintegrate within the community after release and does not pose a threat to the community at large. This parole board also mandates the parole requirements an offender must obey while on community supervision; these provisions are provided to the offender upon release from the correctional institution. If an inmate is denied parole supervision, he or she may be eligible for another trial hearing at a later date.

In the 1970s, discretionary parole release was the most common form of parole release. At that time, inmates typically served open-ended, indeterminate sentences, and state parole boards were able

to exercise complete discretion in the release of inmates. Inmates were released to parole supervision if they could adequately demonstrate that they were rehabilitated and had employment or family available to them within the community upon release. However, the release of inmates to parole supervision utilizing parole board discretionary release eventually changed when research indicated that indeterminate sentencing was quite discretionary. These studies indicated that disparities in sentencing were present when the characteristics of the offense and the offender (e.g., offender race, socioeconomic status, and place of conviction) were taken into account. Many states moved to determine sentencing practices as a result.

Mandatory Parole Release

Another form of parole discharge is mandatory parole release. For many categories of offenses, the amount of time that must be served is legislatively mandated or predetermined at sentencing and often reflects a percentage of the full sentence (e.g., 85% or 2/3 of the full term). Inmates eligible for mandatory parole release are released at the expiration of the specified time frame, regardless of reintegration readiness or the presence of a suitable release plan, provided that the inmate had no infractions while incarcerated. Inmates may also be released to parole supervision when their amount of time served, minus any good time credit, equals the length of their sentence. Offenders released on mandatory parole release must follow parole supervision guidelines as set by a parole board. For some offenses, parole supervision does not have a specified expiration date. For example, many jurisdictions in the United States mandate that persons convicted of certain sex crimes are placed on lifetime parole supervision.

Parole Requirements

Regular Parole Supervision

Inmates discharged from a correctional facility to parole supervision are mandated to meet with their parole officer shortly after release, typically within a 24-hour period. Parolees must adhere to the provisions outlined by the parole board or risk having their parole revoked and be returned to prison. Conditions of parole may include the

payment of restitution, face-to-face office visits with a parole officer, visits to the parolee's approved residence by the parole officer, telephone contacts, employment verification and monitoring, and drug or alcohol testing. It is not uncommon for a parole officer to have a caseload of more than 70 parolees at any given time, but the average caseload within jurisdictions nationally is 38. Nearly two thirds of parolees have face-to-face contact with their parole officers at least once per month.

Intensive Supervision Parole

In some jurisdictions, parolees who are in need of increased surveillance while in the community are placed on intensive supervision parole (ISP). ISP caseloads are smaller than regular caseloads for a parole officer. Parolees on ISP are required to meet with a parole officer more frequently than parolees on regular supervision while also adhering to increased provisions for home visits and drug or alcohol testing. Parolees on ISP may also be placed on electronic monitoring using electronic ankle transmitters and home-based receivers. Few jurisdictions utilize GPS devices. Like other ankle transmitters, the GPS devices are bracelet transmitters that are affixed to a parolee's ankle. The transmitter communicates with satellites and downloads the parolee's location coordinates into a communication center. Electronic monitoring is used to enforce parolee curfews, to determine whether parolees are entering prohibited or restricted areas, and to assess parolee day-to-day movements generally. Parole officers may receive an alert when a parolee is within a prohibited location at a specified time and can initiate contact with the parolee. Electronic monitoring may be statutorily mandated upon release from a correctional facility and has been utilized for sex offenders, parolees with mental illness, and parolees prone to curfew or absconding violations, among others.

Parole Programming

Parolees face a number of issues upon their release from prison. Research indicates that parolees experience a higher prevalence of substance abuse than the general population and have higher rates of mental illness. Parolees are often less

educated and less employable. The majority of inmates leave prison with no savings, no entitlement to unemployment benefits, and no job prospects. One year after release, nearly 60% are not employed in the labor market. Furthermore, many parolees end up homeless and have limited options for housing because they are not welcome in public housing complexes once convicted of a crime.

To combat these issues and to aid parolees in their reintegration into society, many offenders are instructed to attend one or more forms of parole programming. Nearly all jurisdictions provide parolees with some form of drug programming, such as Alcoholics Anonymous or Narcotics Anonymous groups. Many agencies also place parolees into mental health treatment programs if necessary. To prevent homelessness and unemployment, parole authorities often work with other state agencies to assist parolees with finding suitable housing arrangements and legitimate employment. Community resource centers have recently become popular in the United States. These *one-stop shops* provide parolees with daily rehabilitative programming and supervision while they remain living within the community. Offenders assigned to such programs report to the centers during the day and return home at night when programming is complete. Treatment and programming provided by such centers may include educational or vocational training, job placement services, drug abuse education and/or treatment, and life skills training. Parolees may be mandated to attend such centers as a condition of parole upon release or as a halfway back sanction for parole violators.

Parole Revocation and Returns to Prison

If a parole staff believes that a parolee has violated one or more of the conditions of his or her parole, community supervision may be revoked, and the offender may be returned to prison to serve the remainder of his or her sentence. Parolees suspected of a technical violation are arrested and held until a parole revocation hearing is scheduled. At the hearing, the evidence of a parole infraction is reviewed by parole administrators or parole board members. If determined that there is probable cause to suspect a violation has occurred, the parolee is returned to prison. In some instances, parolees found guilty of a technical violation are

returned to parole supervision and provided with a modification of conditions. If probable cause is not found at the hearing, the parolee is returned to parole supervision. According to the Bureau of Justice Statistics, the rate at which parolees were reincarcerated as a result of revocation was 5.2% in 2014. Parolees may also be returned to prison if they have committed a new offense. If convicted of a new crime, parole is automatically revoked without the need for a parole revocation hearing.

Parole Discharge

If an offender does not violate the terms of his or her parole, the parolee is discharged at the expiration of the sentence. In some states, it is acceptable for an offender to continue paying restitution and any monies owed after parole discharge. The U.S. exit rate due to successful completion of supervision was 33 exits per 100 parolees in 2014.

Parole Effectiveness in Reducing Recidivism

More than 60% of parolees return to prison within 3 years of release, either for a parole technical violation, a new offense, or both. The majority of these returns to prison occur within the first 6 months after release. Research indicates that those persons who are most likely to return to prison are those who maintain criminal peer associations, carry weapons, abuse alcohol, and harbor aggressive feelings. Parolees who are employed, have stable living arrangements, and are receiving a drug/alcohol intervention are most likely to succeed on parole. Research exploring the effect of ISP specifically in reducing returns to prison is mixed. Some studies indicate that ISP can reduce recidivism upon prison release and are cost-effective alternatives to incarceration. Other studies have found that parolees sentenced to ISP do not fare any better in the community than parolees on regular supervision and that ISP parolees have higher revocations rates, likely due to the increased level of supervision.

PEDOPHILIA

As defined in the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5)*, pedophilia (known as *pedophilic disorder*) is characterized by at least a 6-month period of sexual fantasies, urges, or behaviors involving a prepubescent child or children. The diagnosed individual must have either acted upon such urges, or the urges cause clinically significant distress or interpersonal difficulty. In addition, to be diagnosed, an individual must be of age 16 years or older and at least 5 years older than the child or children involved in sexual activity. This precludes the diagnosis from being applied to teenagers engaging in consensual sex with same-age peers. Specifiers indicate whether or not the diagnosed individual is exclusively attracted to children; to males, females, or both; or if the disorder is limited to incest.

Although much debate occurred regarding the diagnosis, the diagnostic criteria of pedophilia remained largely unchanged from *DSM-IV* to *DSM-5*. However, the name itself was changed to *pedophilic disorder* to highlight that it is in fact a disorder and not just an atypical sexual interest, which the *DSM-5* suggests be called a *pedophilic orientation*. Although the exact prevalence rate of pedophilia is unknown, it is estimated to be 3–5% in the male population and much lower in the female population. Comorbid disorders may include substance use, depressive disorders, bipolar

disorder, anxiety disorders, antisocial personality disorder, and other paraphilic disorders. After addressing in more detail the critiques of the pedophilia diagnosis, this entry discusses causes and risk factors, assessment, and treatment.

Critiques of the Pedophilia Diagnosis

Major unsolved problems with the diagnosis of paraphilias have been enumerated in the literature. Some of the most important critiques of the pedophilia diagnosis include the following:

- Definitional problems exist. For example, it is unclear whether pedophilia is better construed categorically (e.g., present or absent) versus along a dimension (e.g., present in varying levels of intensity).
- As a diagnostic category, it has yet to demonstrate acceptable predictive validity. Furthermore, the few studies that have examined inter-rater reliability have demonstrated moderate reliability at best. Rates of test–retest reliability remain unknown.
- There is an overreliance in the diagnostic criteria on notoriously problematic self-report. Without evidence that one has acted upon a sexually deviant urge involving a child, the individual may deny experiencing such fantasies or urges and thus not meet criteria for the diagnosis.
- The individual must also experience either distress or interpersonal problems due to the urges (or have acted upon the urges) in order to meet criteria for diagnosis. This issue is especially pertinent in the example of an individual who experiences frequent and intense sexual fantasies or urges involving children but who has *not yet* acted upon them. This individual may not be distressed or experiencing any interpersonal problems related to the urges and thus may actually be more likely to act upon them but still does not meet diagnostic criteria.

Etiology

Most pedophiles report that their sexual interest in children begins in adolescence, around the onset of puberty—similar to the onset of other sexual interests; however, some have disclosed sexual interest in children beginning at even younger ages. Several

theories exist regarding the origin and development of pedophilia. Many wonder whether pedophilia has biological origins or if it is shaped by the environment, and the answer seems to be both. There is some notion that pedophilia may have a genetic component. Because of a lack of twin studies, it is impossible to say whether or not this is truly the case. However, abnormal brain development has been associated with pedophilia. For example, poor cognitive functioning, lower IQ and recall memory, proclivity toward left-handedness, and dysregulated neurotransmitter levels have all been found at higher rates in pedophiles than in the general population, offering some evidence that there could be a neurodevelopmental component to the disorder.

From a learning perspective, conditioning models contend that sexual arousal is a (at least partially) learned behavior. Classical conditioning theory argues that arousal toward novel (hence neutral) stimuli can be produced when such stimuli are paired with an unconditioned sexual stimulus (e.g., nude pictures). There is some empirical support that research participants have been classically conditioned to become sexually aroused to neutral stimuli such as black boots using such a procedure; however, such research contains some methodological issues, and thus, the findings are difficult both to replicate and to generalize to pedophilia. Operant conditioning models, through which scientists have attempted to change sexual arousal responses through reinforcement and punishment, have produced inconclusive results. Thus, it seems as though learning may contribute to the development of the disorder, but it is unknown exactly how.

Research has yielded substantial evidence that sexual offending against children is linked to childhood trauma, especially childhood sexual abuse in the offender's own history. It is important to note that this is not a bidirectional relationship: The majority of children who are abused will not go on to become pedophiles, but many pedophiles do report being abused as children. Studies have found that 28–93% of male pedophiles and 47–100% of female pedophiles report histories of sexual abuse as children, compared to approximately 15% of random controls. However, it is unclear if the experience of childhood sexual abuse actually acts causally as a risk factor for becoming a pedophile.

Scientists have also noted some biological risk factors for pedophilia. Pedophiles have been noted to demonstrate increased concentrations of catecholamines (especially epinephrine) in their neurological systems. Again, it is unclear if this is a causal factor for developing pedophilia or if it is only a correlate. In addition, neurodevelopmental disturbances such as head injury prior to age of 13 years and acquired organic conditions mainly involving frontal and temporal regions of the brain have been described as risk factors.

Assessment

Assessment of Sexual Interest

The most commonly utilized measure of pedophilic interest is penile plethysmography, also known as *phallometry* or *penile tumescence testing*. Such assessments work by presenting various types of sexual stimuli to the individual and measuring penile tumescence (usually circumference) during the presentation. Evaluators then compare penile tumescence in response to deviant (neutral) and nondeviant (e.g., child pornography) stimuli to determine the amount of blood flow and thus what is interpreted to be the individual's sexual arousal to each set of stimuli. Across studies, penile plethysmography assessment for pedophilia has demonstrated sensitivity rates ranging from 42% to 100% and specificity rates ranging from 80% to 100%. Visual reaction time tools have also been used as a measure of sexual interest in this population. Similarly, the individual is presented with deviant and nondeviant sexual stimuli, and his or her viewing time in response to such stimuli is compared. Visual reaction time assessments have been shown to be able to discriminate between child sexual abusers, a community control, and nonchild sexual abusers.

Assessment of Risk and Recidivism

Risk and recidivism assessments generally use clinical or actuarial judgment or a combination of both. Common assessments include the Sex Offender Risk Appraisal Guide, the Historical-Clinical-Risk Management-20, and the Level of Service Inventory-Revised. With regard to predictive validity, it is important to note that the

diagnosis of pedophilic disorder does not necessarily provide information about the individual's likelihood of sexual reoffense. Some research has found no difference in sexual recidivism rates for pedophiles versus nonpedophiles, whereas other evidence shows that the diagnosis does not add to the prediction of reoffense above and beyond that of standard recidivism assessment (e.g., the Rapid Risk Assessment of Sex Offender Recidivism).

Treatment

Biological and Medical

Various medical treatments have been used in attempts to treat pedophilia. Most commonly, attempts are made to lower testosterone in the individual. Such treatments generally have side effects including weight gain, breast development, heart problems, raised voice pitch, loss of muscle mass, depression, and liver damage. Some research supports the use of antiandrogens, including cyproterone acetate and medroxyprogesterone, to reduce testosterone in pedophiles to lower recidivism risk. In addition, gonadotrophin-releasing hormone agonists and surgical castration have been utilized to lower sexual arousal; however, the scientific studies supporting their use lack rigor. Selective serotonin reuptake inhibitors, although originally developed as antidepressants, also function to decrease sex drive, although there is a paucity of research available to determine whether or not these are truly effective for treating pedophilia.

Psychological

Many treatments have not yet been subjected to proper scientific study. Cognitive behavioral interventions have been shown to have modest positive treatment effects, indicated by lower recidivism rates in the treatment group compared to a no-treatment control group. In addition, multisystemic therapy, which involves many environmental factors such as the client's family, has been shown to be beneficial for adolescent sex offenders. Relapse prevention models of treatment, which focus primarily on strategies for reducing risk of future offenses, have generally shown little to no effectiveness in reducing reoffense among

pedophiles. The newer Good Lives model approach to treatment is focused on helping the offender build strengths, as opposed to the typical relapse prevention approach, although further research is needed to determine the effectiveness of this intervention.

PERSONALITY DISORDERS IN INCARCERATED OFFENDERS, TREATMENT OF

Personality disorders are defined in the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition*, as conditions in which the individual has an enduring pattern of inner experience and behavior that deviates markedly from the expectations of the individual's culture, is pervasive and

inflexible, has an onset in adolescence or early adulthood, is stable over time, and leads to distress or impairment. The *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition*, lists 10 personality disorders divided among three clusters, each based on shared phenomenology and criteria. Cluster A (*eccentric disorders*)—paranoid, schizoid, and schizotypal personality disorders—is characterized by a pervasive pattern of abnormal cognition (e.g., suspiciousness), self-expression (e.g., odd speech), or relating to others (e.g., reclusiveness). Cluster B (*dramatic disorders*)—borderline, antisocial, histrionic, and narcissistic personality disorders—is characterized by a pervasive pattern of violating social norms or the rights of others (e.g., criminal behavior), impulsivity, excessive emotionality, grandiosity, or *acting out* (e.g., tantrums, self-abusive behavior, angry outbursts). Cluster C (*anxious disorders*)—avoidant, dependent, and obsessive-compulsive personality disorders—is characterized by a pervasive pattern of abnormal fears involving social relationships, separation, and need for control. Because borderline and antisocial personality disorders (ASPDs) are the best researched of the 10 personality disorders, they are the focus of this entry.

Personality disorders are highly prevalent in the community with estimated prevalence rates of 10–20%. Among incarcerated offenders, the rate is even higher. Personality disorders are associated with significant behavioral and management problems in prison, not surprising because the symptoms of these disorders contribute to offending behavior (e.g., impulsivity, failure to recognize the rights of others) as well as disciplinary problems within jails and prisons. Experts have suggested that treatment that lessens the symptoms of a personality disorder is likely to lessen the offending behavior. Thus, helping patients with a personality disorder to better control their emotions and behavior has direct relevance to addressing the processes that can lead to incarceration.

Borderline Personality Disorder (BPD) and ASPD

BPD is characterized by a pervasive pattern of emotional instability, impulsivity, and disturbed relationships. In contrast, ASPD is associated with

a pattern of socially irresponsible, exploitative, and remorseless guiltless behavior that begins in childhood or early adolescence. These conditions are associated with depression, substance misuse, domestic violence, and psychiatric comorbidity. Family and marital relationships are often disturbed, and health-care utilization is excessive. Both conditions are associated with high mortality rates and excessive suicides. Deliberate self-harm (e.g., cutting or burning) is common in persons with BPD and can result in physical injuries, disfigurement, or lifelong handicaps (e.g., paralysis). In prison settings, both BPD and ASPD show considerable overlap.

BPD has an onset during adolescence or early adulthood and is more common in women than men. The course tends to be most severe during the late teen years and early 20s, when mood instability, impulsivity, and deliberate self-harm lead to a high consumption of health-care resources. BPD symptoms are less stable than once thought, and the disorder may have a better prognosis than other severe mental disorders, such as bipolar disorder. Longitudinal studies show that while many persons may no longer meet diagnostic criteria for BPD in their 30s or 40s and have obtained some stability in their relationships and vocational functioning, problems continue for many as they remain behind their peers educationally and fail in their interpersonal relationships.

ASPD begins early in childhood and is preceded by the diagnosis of conduct disorder. According to *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition*, the diagnosis converts to ASPD at age 18 if behavioral problems have persisted. While chronic and lifelong for most, ASPD attenuates with advancing age in a process often referred to as *burnout*. Earlier onset and younger age are associated with worse outcome, whereas older age is associated with better functioning. ASPD mainly occurs in men, but its prevalence among incarcerated women approaches that of men.

Treatment in Correctional Settings

There are no standard treatments for personality disorders in the community or in correctional settings. That said, for individuals with BPD, psychotherapy has been the mainstay of treatment. There is now strong evidence supporting the

efficacy and effectiveness of a number of manual-based psychotherapies shown to relieve borderline symptoms, improve mood, and lessen the often excessive health-care utilization. The programs include dialectical behavior therapy, schema-focused psychotherapy, transference-based psychotherapy, mentalization therapy, and the Systems Training for Emotional Predictability and Problem Solving program. With the exception of dialectical behavior therapy, none of the programs have been widely disseminated in the community. These programs emphasize group, rather than individual, psychotherapy, which may be advantageous to cash-strapped correctional systems.

Correctional systems have been slow to adapt these treatment programs. Several prisons have implemented pilot programs involving dialectical behavior therapy, but there are no published adaptations. The Systems Training for Emotional Predictability and Problem Solving program has been introduced to several state prison systems without modification. It has been shown to boost mood and reduce borderline-related symptoms, while reducing disciplinary infractions and administrative segregation days. No other program has been systematically evaluated in these settings. Interestingly, Systems Training for Emotional Predictability and Problem Solving has been used successfully to treat patients with comorbid BPD and ASPD, which may give it special relevance in offender populations.

Psychotropic medication is widely prescribed to BPD patients in the community, and this practice is followed in correctional settings even though there are no standard treatments or U.S. Food and Drug Administration–approved drugs. These patients are typically prescribed antidepressants to treat associated anxiety and depression, antipsychotics to help with anger control and suicidality, and mood stabilizers to treat emotional instability. Community-based studies show that many patients with BPD benefit from these treatments, but they have not been systematically evaluated in offenders.

While persons with BPD have benefitted from the many psychotherapies that are now available, the treatment of ASPD remains vexing, and many experts believe the disorder is untreatable. Because research on this question is wholly inadequate, the field is not in a position to conclude that ASPD is

untreatable. In the community, few individuals seek treatment for the disorder, although they often seek care for comorbid psychiatric disorders such as major depression or for problems relating to marital discord, substance misuse, or suicidal behavior.

There are currently no psychological therapies that have been specifically developed to treat ASPD. Individual psychotherapy has been a mainstay of treatment for antisocial patients, and while psychoanalytic treatments held sway for several decades, they have gradually been replaced by cognitive behavioral therapy. The goal of cognitive behavioral therapy is to improve the individual's moral and social behavior by recognizing distorted beliefs and attitudes that interfere with interpersonal functioning or achieving goals. The person is encouraged to identify alternative ways to think and behave and evaluate the outcome. Guidelines are set for the patient's involvement, including regular attendance, active participation, and completion of homework outside office visits. Cognitive behavioral therapy may be helpful to persons with mild ASPD who possess some insight and have reason to improve. Cognitive behavioral psychotherapy has been used to treat the disorder, and early results appear promising. Some experts have cautioned against using psychotherapy, particularly in those who are considered psychopathic by virtue of their extreme antisocial behavior and complete lack of empathy. It is thought that for these persons, their rigid personality structure resists outside influence, and therapy may only give them additional skills to manipulate others. Despite these cautions, there is no empirical evidence that therapy makes antisocial patients worse.

While psychotropic medication is often used to treat people with ASPD, as of 2018, there are no Food and Drug Administration–approved medications. Nonetheless, medication can be effective in treating comorbid psychiatric disorders such as major depression, panic disorder, or attention-deficit/hyperactivity disorder. Treating associated conditions may lead to a diminution of antisocial behaviors. Several drugs have been shown to reduce aggression and temper outbursts, a target symptom of ASPD, and they may be helpful in selected individuals. These medications include the mood stabilizers lithium carbonate and

divalproex, and second-generation antipsychotics. All of these agents have an array of side effects that require careful medical monitoring. Benzodiazepine tranquilizers should be avoided due to their potential to cause disinhibition, thereby fueling *acting out* behaviors. Likewise, stimulants for attention-deficit/hyperactivity disorder should be avoided because of their tendency to be habituating, in addition to having abuse potential in prison.

In addition, many prisons have incorporated special programs for offenders that are designed to target criminal thinking, anger and irritability, trauma and abuse, or other issues that are associated with personality disorders. While widespread, their effectiveness has not been fully evaluated. Clearly, a range of treatments including medication and psychotherapy need to be developed, tested, and refined for correctional settings.

Final Thoughts

The treatment of personality disorders often involves a combination of psychotherapy and psychotropic medication. Inmates should be systematically screened for personality disorders at intake, particularly ASPD and BPD. Those with BPD should be referred for an evidence-based psychological treatment program. While there are several programs to choose from, cost and feasibility will be key issues in their selection. A shorter program may be preferable because of the tendency for prisons to abruptly discharge or transfer inmates. Psychotropic medication may be effective adjunct and should target the individual's comorbid psychiatric disorders.

PERSONALITY PATHOLOGY

This entry presents an overview of personality disorders with an emphasis on those personality disorders that are relevant from a forensic perspective. The psychiatry classification system of the American Psychiatric Association, the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5)*, distinguishes a number of personality disorders, which are clustered in three categories. Cluster A personality disorders, distinguished by features of eccentricity, include paranoid, schizoid, and schizotypal personality disorders. Cluster B personality disorders, characterized by emotionality or unpredictability, include antisocial, borderline, narcissistic, and histrionic personality disorders. Finally, Cluster C personality disorders are distinguished by features of anxiety: avoidant, dependent, and obsessive-compulsive personality disorders.

There are a number of disadvantages of this model of categorizing personality disorders. Most patients diagnosed with a personality disorder meet criteria for more than one. The use of the severity criterion leads to the use of relatively

arbitrary diagnostic thresholds (e.g., 5 of 9 criteria), which results in large heterogeneity within the personality disorder category: Two individuals can meet the criteria for the same personality disorder while having few features of this disorder in common. In addition, inter-rater agreement on the presence or absence of a personality disorder is rather modest, and the relatively low test–retest reliability indicates diagnostic instability. Given these problems, a dimensional trait-based approach rather than this categorical approach was proposed in the task force of *DSM-5*. In the interests of continuity, the existing, symptom-based system of defining personality disorders as distinct categories has been retained. The trait-based system of personality disorders, however, was included in the *DSM-5*, in Section III “Emerging Measures and Models,” noting those measures and models not in clinical use yet, given that they are still subject to further research.

Personality disorders are rather prevalent in the general population with about 10% (range 4–13%) affected. Personality disorders with the highest prevalence include antisocial personality disorder (3.8%) and borderline personality disorder (2.7%). There is considerable evidence, though, that personality disorders are much more prevalent among forensic individuals than in the general community. Based on structured interviews, approximately 66% of the male general prison population and 42% of the female general prison population fulfill the criteria for one or more personality disorders. The antisocial personality disorder is highly prevalent; prisoners are 10 times more likely to receive a diagnosis of antisocial personality disorder than individuals in the general population. The risk of violence in people with any personality disorder is 3 times higher than in people without a personality disorder.

This entry begins with a description of personality disorders that are most prevalent for forensic practice. In addition, it discusses etiological factors including the role of childhood trauma and attachment and genetic factors. Further, the part played by personality disorders in intimate partner violence and in sexual offending is discussed. Finally, this entry discusses the effects of treatment of offenders with personality disorders.

Personality Disorders

Dependent Personality Disorder

Dependent personality disorder is defined as a pervasive and excessive need to be taken care of that leads to submissive and clinging behavior and fears of separation. One of the main components is the aspect of interpersonal dependence. There is a link between dependent personality disorder on the one hand and child abuse and intimate partner violence on the other. Parents who abuse their children are often characterized by problems with underlying dependency strivings. Also, not only victims but also perpetrators of intimate partner violence are often characterized by dependent personality traits. Fear of abandonment is prominent in this personality disorder.

Borderline Personality Disorder

Borderline personality disorder is characterized by a pervasive pattern of instability of interpersonal relationships, self-image, and affects, and marked impulsivity. Borderline personality disorder is overrepresented in prison populations, with 25–50% of incarcerated individuals having this disorder. Many female forensic patients with a diagnosis of borderline personality disorder have committed crimes of a very impulsive nature (e.g., arson). Compared with other personality disorders from Cluster B (dramatic and emotional cluster), patients with borderline personality disorder may show quasi-psychotic thought described as relatively fleeting departures from reality. In a large study in the general population in the United Kingdom, such delusional ideation was prevalent among those in whom antisocial personality disorder co-occurred with borderline personality disorder. Recent evidence suggests that delusions implying threat or harm to the individual are associated with angry affect, which mediates the relationship with serious violence.

Antisocial Personality Disorder

The *DSM-5* diagnosis of antisocial personality disorder is characterized by an enduring pattern of unlawful behavior, aggressiveness, deceitfulness, impulsivity, irresponsibility, reckless disregard for the welfare of others, and/or remorselessness manifest

during adulthood, as well as evidence of conduct disorder in youth. Not surprisingly, prevalence rates of prisoners with antisocial personality disorder are high, ranging between 50% and 80%.

The reliability and validity of this diagnosis has repeatedly been called into question. In fact, antisocial personality disorder has one of the poorest diagnostic inter-rater reliabilities of the *DSM-5* personality disorders. One of the reasons for this may be that clinicians are inclined to assign an antisocial personality disorder diagnosis based on recent criminal behavior, even when patients do not meet full diagnostic criteria.

Although it is often claimed that a diagnosis of antisocial personality disorder predicts violence in prison, there is limited evidence to support this claim. Co-occurrence of antisocial and borderline personality disorders is associated with a broad spectrum of criminal behavior, including violence. There is some evidence that individuals with high antisocial–borderline comorbidity have a higher risk of reoffending following their release into the community than others with a single personality disorder.

Narcissism

Narcissism is defined as a pervasive sense of grandiosity, need for admiration, and lack of empathy. The prevalence of this disorder in the general population is rather low (less than 1%), but this disorder is relatively more prevalent in business leaders and political leaders. Narcissists are especially vulnerable to negative feedback that may challenge their inflated self-view. Psychologists understand narcissism as a dimension that places individuals somewhere along a continuum. Research has revealed that narcissism is strongly associated with information processing deficits, heightened attention and sensitivity to negative stimuli, and emotional dysregulation, which together increase the likelihood of violence. In a study of the general population (National Epidemiology Survey on Alcohol and Related Conditions), individuals classified as high in narcissism and low in self-control were characterized by having engaged in an array of violent acts. These individuals were more than 7 times as likely to have forced someone to have sex against their will.

Schizoid Personality Disorder

Schizoid personality disorder is characterized by a pervasive pattern of detachment from social relationships and a restricted range of expression of emotions in interpersonal settings. Schizoid personality disorder has been found to be associated with violent behavior, and it is a prospective risk factor for recidivism. A number of perpetrators of sexual homicide meet criteria of schizoid personality disorder. There is some evidence that schizoid personality structure is specifically associated with intrafamilial child offending.

Psychopathy

Psychopathy is not a personality disorder; rather, it is a well-known clinical construct associated with norm-breaking and remorseless behaviors, including criminal acts. The term *psychopathy* refers to a condition with distinctive personality features, such as grandiosity, impulsiveness, sensation seeking, lack of empathy and remorse, impaired punishment sensitivity, and antisocial behavior. Psychopathy partially overlaps with features of antisocial personality disorder. Attempts by the *DSM-5* task force to introduce psychopathy to the *DSM* system were unsuccessful.

In forensic practice, psychopathy is most commonly measured using the Psychopathy Checklist–Revised, in which a higher order psychopathy factor bifurcates into two second-order factors: interpersonal/affective (Factor 1) and unstable and antisocial lifestyle (Factor 2). Factor 1 corresponds with the classic description of psychopathy, whereas Factor 2 is more closely related with antisocial personality disorder and measures of criminal behavior.

There is some discussion whether psychopathy should be considered a homogeneous clinical entity given that five of the *DSM-5* personality disorders—antisocial, paranoid, narcissistic, borderline, and histrionic—were found to be associated with high Psychopathy Checklist–Revised scores. Psychopathy as measured by the Psychopathy Checklist–Revised is modestly associated with risk of future violence and general recidivism.

Less than 1% of the general population may have psychopathy, primarily males. In contrast, psychopathy is highly prevalent in the

incarcerated population (25%). Prisoners with psychopathy start offending early in life, commit a disproportionate number of violent crimes compared with prisoners who are not psychopathic, and show higher rates of recidivism. In addition, their use of violence tends to be more instrumental, dispassionate, and predatory than that of other offenders. Although the majority of psychopaths recidivate within a few years after release, about one quarter of psychopaths do not reoffend even after long periods of follow-up time.

A number of studies have examined developmental factors for psychopathy. Both attention-deficit/hyperactivity disorder and conduct disorder (a childhood disorder characterized by rule breaking) are clear risk factors for psychopathy. Prospective studies show that the most severely antisocial children are more likely to receive an adult diagnosis of psychopathy. There is evidence for biological and genetic influences on psychopathic behavior. Neurological deficits have been linked to the inability to regulate behavior. The emergence of new neuroimaging methods has led to a vast increase in the number of neuroimaging studies in individuals with psychopathy and expanded knowledge about the neural mechanisms underlying this disorder. Psychopathy is linked to a broadly distributed network of cerebral regions, including (specific regions of) the prefrontal cortex, amygdala, hippocampus, and the insula. Finally, a few studies have also reported abnormalities in the corpus callosum and the basal ganglia. Although psychopathy is poorly recognized within the formal diagnostic systems, it remains of considerable importance for research and practice in the forensic field.

Childhood Trauma, Attachment, and Personality Disorders

The association between child abuse and neglect and a range of personality disorders, particularly borderline personality disorder and antisocial personality disorder, has been well established. While maltreatment in general has been related to both antisocial personality disorder and borderline personality disorder, there is some evidence that sexual abuse is specifically associated with borderline personality disorder.

Related to this, there is evidence that insecure attachment is a risk factor for personality disorders

and criminal behavior and violence. Insecure attachment is characterized by individuals who view close relationships as harmful. Insecure attachment is strongly related to all types of criminality (i.e., sexual offending, violent offending, nonviolent offending, and domestic violence). There is also some evidence that the combination of dysfunctional attachment and childhood trauma may lead to personality disorder. Cumulative exposure to childhood trauma is associated with an increased risk of conduct disorder and criminal behavior in adults. More specific to child molesting, several studies found limited parental warmth and protection and insecure attachment are vulnerabilities in the development of child-molesting behavior.

Genetic Influence

Aggression is considered to be partly heritable. Research has revealed that there is a concentration of perpetrators of crime in families: Half of all crime is committed by fewer than 10% of families. It is now generally accepted that biological factors play an important role in the etiology of antisocial behavior and, subsequently, also in criminal behavior.

Individual differences in antisocial and criminal behavior are explained by both environmental and genetic factors, with genetics estimated to contribute about 50% of the variance. It is likely that an additional 15–20% of this behavior can be explained by environmental factors shared by families. To complicate matters, however, environmental influences can generate changes in gene function, which result in modifications of neuronal functioning that influence behaviors.

There is some evidence that genes may play a protective role in the development of antisocial behavior. Adoption and twin studies found that bad parenting had relatively little effect on antisocial behavior in children who were at low genetic risk. Generally speaking, genetic links to crime are generally very small and cannot be used for clinical recommendations in forensic practice.

Intimate Partner Violence

Intimate partner violence can be expressed as psychological, physical, or sexual abuse; all harm the well-being of the partner. Several subtypes among

batterers have been found, which differ regarding severity of marital violence, generality of the violence (toward the partner only or toward others as well), personality disorders, substance abuse, and attachment style. Several studies found that male batterers are more (often) insecurely attached as compared with nonbatterers. More specifically, male batterers are predominantly preoccupied or fearfully attached. Studies have shown that insecure attachment is related to dependency, impulsivity, low levels of empathetic concern, lack of self-esteem, and high levels of jealousy. The self-esteem of insecurely attached persons is dependent on other people's approval, and the slightest indication of disapproval, criticism, or disinterest can strengthen their low self-esteem.

So far, studies comparing batterers and nonbatterers regarding personality characteristics generally found differences between these two groups. That is, most studies found that compared with nonbatterers, wife batterers score higher on abandonment anxiety and impulsivity. Furthermore, a number of studies have found that male batterers have lower self-esteem than nonbatterers and that low self-esteem is related to violence and predictive of abusive behaviors. There is also some evidence that narcissism, borderline personality disorder, and antisocial personality disorder are related to intimate partner violence. High antisocial and borderline personality traits in intimate partner violence perpetrators were associated with a high risk of recidivism. In intimate partner violence perpetrators with both antisocial and borderline personality traits, the risk of recidivism was higher than in those with only one of these traits.

Sex Offenders and Sexual Homicide

Criminal sexual behavior comprises a wide spectrum of actions across a variety of situations. Sex offenders cannot be simply classified because they are heterogeneous, both in terms of etiological factors and degree of severity, which has led to distinct sex offender profiles. Mixed sex offenders are more likely to demonstrate psychopathy-related traits than intra- or extrafamilial child sex offenders, rapists, and non-sex offenders.

The empirical literature on sexual homicide has positioned the sexual murderer as a unique type of

offender. Different models have been proposed to explain sexual homicide. There is some evidence that personality disorders and personality traits may also play a part in the type of sexual offenses. A number of studies investigated the differences in personality between nonhomicidal sex offenders who inflicted (severe) physical injuries and sexual homicide offenders who killed their victim. Generally, studies comparing differences between nonhomicidal sex offenders and sexual homicide offenders found that sexual homicide offenders had more problematic childhood and adolescence, were more frequently diagnosed with antisocial and schizoid personality disorders, and had more maladaptive personality traits. Although some sex offenders may be largely influenced by situational factors and end up killing the victim, there is some evidence that personality disorders and personality traits (e.g., impulsivity/lack of self-control) may also explain why some sex offenders kill their victims. Serial sexual homicide offenders were more likely than single offenders to have narcissistic and/or schizoid traits.

Treatment

Generally, clinicians are highly pessimistic about the results of psychological treatment of antisocial personality disorder and psychopathy; however, a negative attitude with respect to possible outcome of psychological treatment may not be justified. The conclusions drawn from several meta-analytic studies on the effectiveness of treatment outcome studies were that treatment reduces recidivism rates and that cognitive behavioral treatment is more effective in reducing recidivism than psychodynamic and nondirective interventions. In general, there is some consensus that structured treatment, aimed at the alterations of cognitions and behaviors, is more effective in offender populations than less structured treatment. Such cognitive behavioral treatment programs typically focus on identifying and challenging cognitive distortions associated with crime and violence, enhancing perspective taking; improving emotional regulation and coping; teaching interpersonal skills, conflict resolution skills, and problem-solving skills; and developing relapse prevention plans. A few randomized controlled trials have investigated the effects of psychopharmacology on antisocial

personality disorder, but the few studies conducted do not allow any conclusions to be drawn about the use of pharmacological interventions.

A few studies found that patients with high levels of psychopathy had adverse responses to psychotherapy (i.e., they did worse in terms of reoffending after treatment had ended). Presumably, programs that are beneficial for non-psychopathic offenders are not effective or may be even harmful for psychopaths.

For borderline personality disorder, schema-focused therapy (i.e., psychotherapy based on a combining theory and techniques from previously established therapies) is an evidence-based treatment. In preliminary studies in a forensic setting, however, results were less encouraging. In Dutch forensic settings, schema-focused therapy is specifically adapted to the population, and a specific schema-focused therapy model is developed to focus on personality traits, which incorporates fluctuating emotional phases that easily result in aggressive, impulsive, or antisocial behavior. Results reveal that criminal behavior is often first preceded by feelings of vulnerability and abandonment, loneliness, and states of intoxication. Criminal behavior itself is characterized by states of impulsivity, anger, and the use of overcompensatory strategies involving threats, intimidation, and aggression. Yet this is still ongoing research and it remains unclear whether this specific forensic model leads to less recidivism in forensic settings. Another evidence-based approach for patients with borderline personality disorder is dialectical behavior therapy. To date, this treatment has not been evaluated in controlled studies, but research has indicated that forensic patients do not differ on borderline personality disorder variables from nonforensic patients.

Conclusions

Personality disorders are much more prevalent among forensic individuals than in the general community. Prisoners are 10 times more likely to receive a diagnosis of antisocial personality disorder than individuals in the general population; borderline personality disorder is also overrepresented in prison populations. Psychopathy, characterized by grandiosity, impulsiveness, lack of empathy and remorse, and antisocial behavior, partially overlaps with

features of antisocial personality disorder. Individual differences in antisocial and criminal behavior are explained by both environmental and genetic factors, with genetics estimated to contribute about 50% of the variance. Insecure attachment is a risk factor for personality disorders and is strongly related to all types of criminality. Cumulative exposure to childhood trauma is associated with an increased risk of criminal behavior in adults. Psychological treatment reduces recidivism rates, and structured treatment, aimed at the alterations of cognitions and behaviors, is more effective in offender populations than less structured treatment.

PHYSICAL AND MENTAL HEALTH TREATMENT

When working with prison inmates, mental health professionals often take a holistic and multidisciplinary team approach, assisting medical personnel with the appropriate assessment and treatment of physical and mental health concerns that will lead to effective clinical interventions. Consistent with a biopsychosocial model, it is important for such professionals to be aware of the unique aspects of inmates' psychological makeup, social history, history of illnesses, and their current medical conditions in order to treat their mental and physical health needs. This entry considers the role of combined treatment for various populations of prison inmates.

Older Adult Inmates

As the number of older adult prisoners increases, patients with dementia and Alzheimer's disease may be found within the confines of prison. The control and structure of the prison routine may be helpful for patients with dementia, as consistency and stability can assist them in performing daily living skills and in reducing confusion; however, a

multidisciplinary team approach can further improve outcomes. For example, providing visual memory cues, such as a calendar or a daily schedule, as well as photos of loved ones, can be useful compensatory strategies. Such inmates may be more sensitive to changes in their routines and may be overly moody or anxious; thus, mental health professionals may need to provide additional counseling. In addition, properly trained and supervised *inmate companions* can help to watch and assist those who may get confused or lost or are at risk of falling.

Additional combined treatment includes providing cognitive exercises and activities and facilitating occasions to socialize with others. The former can help these patients with their memory, executive functioning, and disorientation issues, whereas the latter can reduce loneliness. Educating staff members on the benefits of patience, clear and slow communication, and strategies for navigating aggressive behaviors in a calm, controlling, and nonconfrontational manner can reduce their stress and address any security concerns that may arise between inmates and caretaking staff.

Inmates With Addictions and Unhealthy Lifestyles

Many inmates have a history of addiction that oftentimes results in long-term physiological consequences. These inmates may present with diseases such as hepatitis, diabetes, dental concerns, and liver concerns. They may also be dealing with a variety of mental health concerns possibly exacerbated by previous substance abuse. Thus, it is important for medical personnel to be aware of past addictions when prescribing medications, especially psychotropic medications (i.e., drugs used to affect the mind, mood, or behavior) used for the treatment of severe mental illness. The dispensing of medications that are known to be commonly abused (e.g., opioids, narcotics) should be well controlled and monitored. Furthermore, if possible, medicines of potential abuse should be crushed and mixed with water when given to the inmate to ensure that the inmate actually ingests the drug and isn't *cheeking* it (holding the drug in one's mouth instead of swallowing the pill).

Drug treatment services can be provided to assist this population with the emotional and

behavioral aspects of their addictions. Such treatment consists of education about addictions, identifying addictive patterns, and developing strategies for avoiding maladaptive patterns. Psychoeducation on basic health, diet, and exercise can also be provided to encourage the development of a healthy lifestyle—one conducive to remaining drug free and to enhance physical functioning. Inmates may also benefit from education on healthy relationships, good communication strategies, handling unpleasant emotions in a healthy and effective manner, and stress management.

Some inmates have a history of living an unhealthy lifestyle, as obesity and associated illnesses are prevalent. These inmates may be unaware of good dietary choices and the importance of exercise. For those who would like to learn and incorporate a healthy lifestyle, a nutritionist can provide valuable information and assistance with healthy food choices, and a psychologist can provide assistance with motivation. Cognitive and behavioral techniques, as well as the provision of support, can assist inmates with improving their choices in relation to their physical health.

Inmates With Significant Injuries and Medical Illnesses

Some inmates have significant prior injuries—for example, having been involved in accidents, having been seriously injured by others, or having suffered gunshot wounds—and some may have terminal illnesses or illnesses with associated pain that they must manage. Some inmates may be paralyzed and using a wheelchair and may require assistance with daily living skills.

Inmates with significant injuries may need physical and occupational therapy to assist them with effective and compensatory strategies and emotional assistance to help them grieve the loss of physical functioning. For inmates with pain issues, a mental health professional can provide psychoeducation on pain management, including monitoring pain levels and contingencies associated with increased and diminished pain. In addition, these inmates can be taught relaxation strategies as well as distracting techniques to assist them with pain management.

Restful and satisfying sleep assists with good health, but pain, stress, lack of mobility, and

boredom may make it difficult for such inmates to sleep well. Treatment includes psychoeducation on strategies to assist with sleep, such as maintaining a regular sleep schedule, getting out of bed when unable to sleep for too long, staying away from caffeine in the later afternoon, meditation and progressive muscle relaxation techniques, and maintaining a quiet environment prior to bedtime. In addition, to combat boredom, recreation staff can provide opportunities for inmates to engage in enjoyable and healthy activities, which can give them a sense of purpose, distract them from negative emotions, and provide forums for healthy socialization.

When inmates are emotionally vulnerable, desperate, or seeking spiritual validation, behavior modification techniques can encourage their engagement in self-care. Techniques such as cognitive reframing can help inmates view their role in society in a more healthy way, resulting in an improved sense of self-worth and value.

Inmates with terminal illnesses can be encouraged to find closure in their relationships. At times, this may mean attempting to reconcile with family members who have stopped communicating with them. If an inmate is unable to contact someone with whom they would like to connect, they can be encouraged to write a letter and perhaps give it to someone they trust for future delivery to the intended party. Such a letter may entail taking full responsibility for the offense for which they are serving time and apologizing for any hurt they may have caused. Psychologists can help inmates fully appreciate the consequences of their actions and how those consequences have impacted them, their lives, and their loved ones. Issues of grief and loss that may arise can be addressed with a psychologist as well.

Inmates with terminal illness may also benefit from regular services provided by religious services staff. For example, religious counseling may help these inmates address any spiritual issues they may be facing as a consequence of their prognosis, including anxiety related to their own health and death, which may increase when one of their peers dies. Staff presence at memorial services held for deceased inmates may give prisoners more confidence in the resources and support available to them, which can be helpful for morale, mental health, and general engagement in health care.

As mentioned earlier, mental health support can help those with significant injuries and illness grieve the loss of physical functioning, but such support can also help them review mistakes they have made and the relationships that have been lost and reconcile their life's end in prison. As these inmates near the end of their life or grieve their physical losses, they may be ready to examine the manner in which they have lived their life—both good and bad. Giving them an opportunity and forum for thorough and insightful end-of-life reflection is incumbent upon psychologists working with this inmate population.

Social Support

Social support has been shown to be helpful for good health, longevity, and recovery from illness and surgery. Prison inmates have limited access to their loved ones, so they may rely on each other for support. Psychology services can provide appropriate therapy groups that encourage support and effective communication. Group members can benefit from learning what constitutes a healthy and positive relationship and learn healthy communication skills to facilitate a healthy group process. Such therapy groups focus on providing a forum where inmates feel as though there are others who care about them and their situation, building a social network within their current environment, and improving their sense of worth.

PLEA NEGOTIATIONS

Approximately 90% of all criminal cases in the United States are pled guilty, and a majority of these cases are a result of plea negotiations. Plea negotiation is defined as pleading guilty in exchange for something of value from the prosecutor—generally, a reduction of charges or counts or a more favorable sentence recommendation. There is a great amount of psychology in determining the factors that influence the negotiation process. It is important to understand the term *plea negotiation* and identify the different types of pleas and plea negotiations—all of which this entry discusses. In addition, this entry addresses the role of both the prosecutor and defense attorney in this plea negotiation process. Finally, this entry addresses legally relevant and legally irrelevant influences of the plea negotiation decision.

Understanding Plea Negotiation

The term *plea negotiation* suggests a contractual agreement between two parties with one party making an offer to give something of value in exchange for something of value in return from the other party. In a sales contract, for example, a seller will offer a product of a certain value in exchange for some monetary payment from the buyer. In some cases, the buyer can negotiate the terms of the purchase either reducing the sale price or changing the quality or quantity of the item. The buyer can also negotiate any of these terms in return.

The negotiation is a type of bartering system between the two parties. In criminal justice, the two parties are the prosecutor, who represents the state or commonwealth, and the defense attorney, who represents the defendant. For the prosecutor, one of the goals is to seek and carry out justice for the community and/or victim. For the defense attorney, one of the goals is to obtain the best *deal*

for his or her client. Therefore, in plea negotiations, the prosecutor desires to obtain a conviction with a level of punishment to obtain the kind of justice the victim and/or community desires. The defense attorney seeks to minimize the impact of this justice on his or her client.

Much like a contractual negotiation, each party—prosecutor and defense attorney—holds a certain amount of authority. On one hand, the prosecutor determines the type of charge, the severity of charges, the number of charges and/or counts of a particular charge, and the type and/or length or amount of a recommended punishment. On the other hand, the defense attorney determines if the case will go to trial or not by accepting and/or negotiating the terms the prosecutor offers.

A plea agreement, therefore, is a defendant's guilty plea in exchange for a reduced charge or number of counts or a reduced sentence. Both parties give something of value in exchange for something of value in return.

Types of Pleas

All plea negotiations—if successful—require two things. First, the defendant must plead guilty to the terms negotiated. Second, the judge must approve the terms of the plea negotiation. In order to understand plea negotiations, though, it is important to understand the different pleas one can make at arraignment—the part of the criminal court process in which the prosecutor must give the defendant notice of official charges and the defendant makes a plea in response to those charges.

The first type of plea one can make in open court is *guilty*. Pleading guilty necessitates the defendant to admit wrongdoing and accept the punishment required for the charges made by the prosecutor. The second type of plea during one's arraignment is *not guilty*. This plea communicates to the court that the defendant does not admit guilt and wants to contest the charges in a trial. The prosecutor, therefore, carries the burden to prove that the defendant committed the crime; the level of that burden is beyond a reasonable doubt, which is approximately 85–90% certainty.

A third type of plea a defendant can make during arraignment is *nolo contendere*—otherwise

known as *no contest*. This plea allows the defendant to accept the punishment without admitting guilt. This plea protects the defendant from civil lawsuits and additional punishment for subsequent criminal charges. A fourth and related type of plea is called an *Alford plea*—named after the U.S. Supreme Court case titled *North Carolina v. Alford* (1970)—which allows the defendant to accept the punishment given that the evidence is enough to find guilt in a trial, but the defendant does not have to admit guilt. Although there is a possibility that the charge or charges might be dismissed by the judge for insufficiency of evidence, this type of plea allows for subsequent criminal or civil action unlike no contest. Pleas of guilty, not guilty, and Alford pleas can play a significant role in plea negotiations. Two more pleas—*not guilty by reason of insanity* and *guilty but mentally ill*—can be made in open court that address one's mental status at the time of the crime, but they generally do not involve plea negotiations.

Types of Plea Negotiations

Plea negotiations in a criminal case are defined as pleading guilty in exchange for something of value from the prosecutor. There are several different types of plea negotiations based on what the prosecutor could do. These different plea negotiations are charge negotiations, count negotiations, and sentencing agreements.

Charge negotiations and count negotiations are directly controlled by the prosecutor. Charge negotiations take multiple forms. First, a defendant can plead guilty in exchange for a reduced charge. For example, the prosecutor reduces the severity of the charge—from a felony to a misdemeanor, for example—in exchange for a guilty plea. Second, a charge negotiation can include a reduction of the number of different charges. For example, the prosecutor reduces three different offenses down to one offense.

Similarly, the defendant and the prosecutor can enter into count negotiations. The defendant may have been originally charged with multiple counts of one particular offense. In a count negotiation, the defendant may agree to plead guilty to one count of that particular offense in exchange for the prosecutor dropping the other counts. These

decisions are at the discretion of the prosecuting attorney.

A final type of negotiation is called a *sentencing agreement*. In this plea negotiation, the defendant agrees to plead guilty in exchange for a more lenient sentence recommended by the prosecutor to the judge without reducing the charges and/or counts. Since the sentence is ultimately determined by the judge and/or jury, the prosecutor cannot guarantee this term of the plea negotiation. However, based on the sort of day-to-day shared environment between prosecutors, defense attorneys, and judges—known as the *courtroom workgroup*—the defendant can rely upon this sentence agreement.

Roles of the Prosecutor and Defense Attorney

To understand plea negotiations in the U.S. criminal justice system, it is important to understand the roles played by the attorneys involved—namely, the prosecutor and the defense attorney. Each plays a role in making the decision to enter into a plea negotiation but have different orientations and levels of authority in this negotiation process.

The role of the prosecutor is to prove that the defendant fulfilled the requirements of a particular crime (known as *elements*) and that the evidence supports this conclusion beyond a reasonable doubt—a heavy burden. The prosecutor in most states is a political figure, that is, prosecutors are either elected or appointed by an elected official (e.g., governor). Therefore, they are accountable to a certain group of constituents in this political climate. From a sociopolitical perspective, the prosecutor has additional strains than merely winning the case. To be certain in obtaining convictions, prosecutors rely on guilty pleas and enter into plea negotiations even if trial may be the desire of the community.

The prosecutor holds a vast amount of discretionary power in the courtroom. The prosecutor can decide to charge or not, to determine the severity of those charges and how many charges or counts to apply in the case. The prosecutor can use his or her discretionary authority to request a certain pretrial release—bail. The prosecutor can decide whether to charge the defendant with an

enhancement or even the death penalty. Finally, the prosecutor uses his or her discretion to enter into plea negotiations and to determine the terms of that negotiation.

The defense attorney has a different role in the criminal case. Since the prosecutor must prove the requirements of the crime beyond a reasonable doubt, the role of the defense attorney is to question evidence presented by the prosecutor and provide evidence that would produce reasonable doubt. However, the defense attorney has a different set of pressures. First and foremost, the defense attorney must advocate for his or her client—the defendant. Unlike the prosecutor, the defense attorney does not have the added political pressure to win the case. On the other hand, the defense attorney does not have the type of discretionary power and authority in the case as does the prosecutor. The prosecutor sets the case in multiple ways; the defense attorney typically can only respond to the case. Finally, a defense attorney can either be public or private, which adds its own type of pressure. Private defense attorneys are paid by the client, whereas public defense attorneys are paid by the state or commonwealth and provided to the defendant if the defendant cannot afford an attorney, which is a right protected by the Sixth Amendment to the U.S. Constitution as interpreted by *Miranda v. Arizona* (1966).

Factors Influencing Plea Negotiations

Both the prosecutor and defense attorney can be interconnected in the courtroom workgroup whereby both sides have an understanding of the *going rate* of what the case is worth. Given this regular working environment and the predetermined going rate of the value of the case, plea negotiations can become routinized. Many factors can influence this negotiation process regardless of the routine nature of these decisions.

The most influential factor on plea negotiations is the strength of the evidence in the case. If the evidence is strong, then the certainty of conviction is high, and therefore, the need to negotiate a guilty plea is greatly reduced. There is great debate about what makes evidence strong or weak. Does the presence of DNA evidence make evidence strong? Does the sheer volume of evidence make evidence strong? Is eyewitness testimony found more

credible coming from some sources compared to others? How is strength of evidence assessed?

Strength of evidence is a factor that is known as a legally relevant factor because the determination of whether a case is convictable is a legally rational factor. There are other factors that are less legally relevant. For example, the sociopolitical factors and pressures both the prosecutor and defense attorneys feel would be classified as less legally relevant to serving justice.

Another legally irrelevant factor on plea negotiation is whether the defense attorney is private or public. Some argue that attorneys might be more motivated to advocate for defendants if they earn higher wages, that is, private attorneys are stronger advocates than public defense attorneys. If private attorneys are viewed as stronger advocates, then the plea negotiations are more favorable for defendants. In addition, the caseload for public defense attorneys is typically much higher than private attorneys because most defendants cannot afford a private attorney.

With the combination of political pressures, courtroom workgroup, affordability of certain types of attorneys, and the mounting caseloads, Rodney Uphoff summarized three types of defense attorney personalities in plea negotiations: zealous advocate, double agent, and beleaguered dealer. The zealous advocate personality fits the private attorney the best in that the private attorney stops at no cost to advocate for his or her client without regard to salvaging any relationship in the courtroom workgroup. The double agent plays both sides in trying to salvage the relationships with different prosecutors in order to assist his or her cases in the long term but attempts to convince his or her client that he or she is a strong advocate. Finally, the beleaguered dealer is frustrated by high caseloads with low resources and is reluctantly willing to engage in a high volume of plea negotiations. The beleaguered dealer is an often-used representation of the public defender.

Finally, many would argue that the factors that are the most legally irrelevant are demographic characteristics of the defendant. The marginalized characteristics of the defendant may influence the prosecutor's negotiating practices in obtaining a guilty plea. For example, are Black defendants less likely to obtain a favorable plea negotiation than White defendants? Are male defendants less likely

than female defendants? Are younger defendants less likely than older defendants? These factors are still debated today.

POLICE INTERROGATIONS

A police interrogation involves a police officer interviewing someone who is believed to have committed a crime. The officer who conducts the interview is often called *an interrogator*, and the person being interviewed is commonly referred to as *a suspect*. The evidence pointing to the guilt of the suspect can range from mere suspicion to absolute certainty. Interrogators may differ on their goal when talking to the suspect. For instance, the interrogator may simply wish to obtain an admission of guilt from the suspect (i.e., confession), or the interrogator may wish to obtain a full story about the suspect's involvement in the crime (or the suspect's whereabouts when the crime was committed). Beyond those differences, there are also differences in how interrogations are conducted, as discussed in this entry.

Third-Degree Approach

Until the 1930s, it was common for police officers to use *third-degree* tactics when interrogating

suspects. Third-degree tactics included different types of physical force and abuse (e.g., hitting), isolation, and deprivation of basic necessities (e.g., food). Interrogators apparently used these harsh tactics because they perceived themselves to be at war with crime and that the third degree was the most effective weapon in winning the war (i.e., securing confessions). Third-degree tactics were used because officers believed they only interrogated guilty individuals. That is, they failed to believe that they sometimes interrogated innocent people. Therefore, such harsh tactics were seen as a necessary evil in making uncooperative suspects talk. Police organizations came to realize that harsh tactics produced unreliable information, elicited unreliable confessions, lowered public confidence in policing, and impeded the professionalization of policing.

Accusatorial Approach: The Reid Technique

The use of third-degree tactics was mostly obsolete by the mid-1960s. Interrogations are now based largely on the personal experiences of Chicago polygraphist John Reid. The Reid Technique (Reid) has been taught to hundreds of thousands of investigators worldwide. Reid consists primarily of a behavioral analysis interview and a nine-step interrogation.

The behavioral analysis interview aims to identify guilty individuals who need to be interrogated. It is assumed that guilty individuals will answer questions in a way that is distinct from innocent individuals. Specifically, guilty people are thought to provide evasive and ambiguous answers. Empirical tests of the behavioral analysis interview have shown that it is not effective, and furthermore, training officers to use Reid-advocated cues impairs their ability to separate truth tellers from liars.

Those who are believed to be guilty are exposed to a nine-step interrogation. The nine-step technique aims to elicit a confession through a psychologically pressure-filled interaction.

Step 1 involves a direct, positive confrontation with a suspect. Interrogators are taught to state their unwavering belief in the suspect's guilt and to follow the confrontation with a pause so that the suspect's response can be scrutinized. Interrogators are taught to examine an *evidence folder*

(which can contain blank pages) to communicate to the suspect that the interrogator has proof of guilt and to use a transition statement (also known as a *theme*) that provides the suspect with a reason for why the interrogation is taking place (i.e., the suspect's guilt is assured).

Step 2 pertains to the development of a theme or a reason that the suspect committed the crime. Interrogators are taught that the chosen theme should reinforce the suspect's rationalizations for committing the crime in order to make it easier for a guilty person to overcome any hesitations associated with admitting his or her criminal involvement. If the suspect continues to reject the themes, interrogators are taught to use different themes in an effort to find one that the suspect will find acceptable.

Step 3 requires the interrogator to prevent suspects from denying involvement in the crime. For example, interrogators may reconfirm their belief in the suspect's guilt and reiterate the proposed theme, all while preventing denials from being voiced. Allowing initial denials of criminal involvement presumably reduces the likelihood of obtaining a confession at a later stage in the interrogation.

Step 4 involves the interrogator overcoming objections, or excuses given by suspects as to why they could not, or would not, have committed the crime. Because it is assumed that only guilty suspects verbalize objections, a movement from denials to objections is assumed to be a good indication of deception. Unlike denials, interrogators are taught that objections should be permitted because they can be used to further the development of a theme—namely, by providing the interrogator with an opportunity to turn the objection around to match the proposed theme.

Step 5 aims to obtain and retain the suspect's attention. After being discouraged from expressing denials and having their objections turned around to support the interrogator's proposed theme, suspects may psychologically withdraw. At this point, interrogators are taught to regain the suspect's attention and increase pressure—for example, by inching their chair forward into the suspect's physical space.

Step 6 requires interrogators to recognize and overcome passive moods. After the suspect's attention is gained, the suspect is presumed to be more

willing to listen but may appear physically defeated. At this stage, interrogators are taught to concentrate on a specific theme, display understanding and sympathy, and urge the suspect to tell the truth. Interrogators are taught to use such techniques until the suspect shows signs of considering whether to tell the truth.

Step 7 is the presentation of the alternative question. An alternative question presents the suspect with a choice between two explanations for the commission of the crime (e.g., Did you plan to kill him or was it an accident?). One of the explanations is face-saving and one more reprehensible, but both involve an admission of guilt. Alternative questions allow a suspect to save face while providing the interrogator with an incriminating admission.

Step 8 attempts to get the suspect to verbalize the details of the offense. After a suspect makes an admission of guilt, the interrogator is encouraged to show signs of sharing the suspect's relief and to draw the suspect into a conversation to fully develop the confession. When general acknowledgment of guilt is achieved, the interrogator is encouraged to return to the beginning of the narrative and obtain information that can be corroborated.

Step 9 is the final step whereby the oral confession is converted into a written confession. This final step is thought to be important because it is assumed that a written confession reduces the possibility that an individual will retract the confession and, if he or she does, it helps to ensure the confession will lead to a conviction.

Research has shown that some of the persuasive tools in Reid's toolbox increase the chances of obtaining false confessions. In a classic experiment, commonly referred to as the *ALT KEY paradigm*, Saul Kassin and his colleagues found that false confessions could be elicited from students through psychological manipulation. Other researchers have replicated these findings using the same design and also using more realistic and pressure-filled scenarios.

Humane Approach: The PEACE Model of Investigative Interviewing

PEACE is an acronym that stands for the stages of interviewing, which include (a) Planning and Preparation, (b) Engage and Explain, (c) Account,

(d) Closure, and (e) Evaluation. Under the PEACE model, the term *interrogation* is replaced with the term *investigative interview*, as the approach is based on a humane and ethical philosophy. In direct contrast to accusatorial approaches, interviewers are taught to collect information before making decisions, which is more akin to hypothesis testing in science. The role of interviewers who utilize PEACE is that of objective fact finders, as they are taught to be open-minded, not to attempt to detect deception through behavioral cues, and not to lie or use psychologically coercive tactics to manipulate interviewees.

Planning and Preparation involves getting interviewers to create a written plan that documents the following: How information obtained will contribute to the investigation; interviewee information (e.g., vulnerabilities); legal safeguards to be administered; and objectives (e.g., points to be disproven). Interviewers are also taught to consider practical arrangements (e.g., where to conduct the interview), develop a timeline of events, prepare the opening question and subsequent questions that emerge from an analysis of existing evidence, create an interview outline, and plan for eventualities (e.g., no comment interview).

Engage and Explain involves engaging the interviewee in conversation and explaining what will happen during the interview. Interviewers engage the interviewee by personalizing the interview, building rapport, engaging in self-disclosure, and acting in a respectful and considerate manner. Interviewers are taught to be accommodating by making sure the interviewee understands the purpose of the interview and to be ethical by providing the required legal safeguards in a clear manner. This phase of the interview also involves telling the interviewee about the outline of the interview, the routines that will be followed (e.g., note-taking), and expectations of both parties (e.g., limited interruptions).

Account involves asking an open-ended invitation that elicits a step-by-step account of the interviewee's whereabouts during the material time frame (i.e., a period of time that encompasses the time when the crime was committed) or asks the interviewee to provide a detailed answer that takes into account the evidence that both the

interviewee and police know about (known as a *trailer question*). The goal of the first part of this phase is to obtain an uninterrupted account of their version of the events. If a free narrative is not forthcoming, interviewers are taught to ask planned questions that attempt to understand the detailed movements and actions of the interviewee during the material time frame.

Interviewers are encouraged to take notes on the various topics (e.g., people, locations, actions, times) regarding the incident. The interviewer should then explore each of the identified topics in a structured manner by (a) opening up a topic through the use of an open-ended invitation (e.g., starting with *tell, explain, describe*), (b) probing the account (who, what, where, when, why, and how), and (c) summarizing all of the information obtained about a particular topic. This systematic process is repeated until all of the topics identified from the interviewee's free narrative have been explored. Once the interviewer believes that all topics have been covered in detail, a summary of the entire interview is provided to the interviewee and checked for the interviewee's agreement of the account.

Interviewers are then taught to consider whether or not the interviewee's account is consistent with the available evidence. If a discrepancy is identified, the interviewer may challenge the interviewee at the end of the interview. A challenge is a clarification-seeking task where the interviewee is given an opportunity to explain any discrepancies. The number of challenges depends on the amount of discrepancies identified. Interviewers are also taught to recognize resistance (e.g., receiving evasive answers) and are taught to handle it in an ethical and appropriate fashion (e.g., not engaging in arguments).

Closure occurs when the interviewer has asked all of his or her questions, and all of the objectives have been achieved. Interviewers summarize the main points of the interview, provide the interviewee with the opportunity to correct or add any information, and explain what will happen in the future.

Evaluation is the final phase in which interviewers consider the effect of new information on the investigation and how the information is consistent with the available evidence. Interviewers are encouraged to conduct self-evaluations of

their performance, and supervisors provide constructive feedback as well.

POLICE LINEUPS, PSYCHOLOGY OF

The police lineup involves the presentation of multiple individuals (a suspect and a group of known innocent individuals known as *fillers*) to a witness in order to determine whether or not the witness recognizes the suspect as the perpetrator of the crime. The purpose of presenting a suspect within a group of other individuals is to increase the likelihood that a witness who identifies the suspect is doing so because the suspect is the perpetrator and not simply because the witness feels compelled to identify someone. A properly

constructed and administered lineup provides information regarding the likelihood that the suspect is the perpetrator. In U.S. agencies, lineups are typically administered with photo spreads: A photograph of the suspect is presented among photographs of persons of similar appearance. Historically, physical lineups containing a set of people, not photographs, have been used, but their use today is extremely rare. Lineups as a means of criminal identification have been used since the 1800s, but the refinement and sophistication embedded in the policies and procedures that have come about in the 2000s are based largely on empirical science conducted since 1970. This entry discusses considerations and factors involved in administering lineups and presents evidence-based recommendations for conducting police lineups.

Memory Considerations for Police Lineups

All identification procedures are founded on the premise that the witness actually saw and remembers the offender. While obvious, this assumption is complex. Seeing is one thing, forming a memory rich and detailed enough for a reliable identification weeks later is another. An optimal environment for forming a memory would require observing an undisguised face moving slowly in angle and posture at a near distance (5'–10') for a short time (~10") under good daylight illumination in the absence of threats to the observers' life and safety, without competing demands on one's attention to the face observed and without intervening objects (e.g., bushes, screens, glass or plastic media providing reflections). The memory formed is nearly always better if the face is of the same appearance group as the observer: A contrast (e.g., African American or European American faces for Mexican American observers, and vice versa) leads to less effective information gathering from the face.

A large scientific literature exists on the factors affecting perception and memory for faces. However, sorting out their influence in a particular instance is not straightforward. The further the conditions of viewing and memory preservation are from optimum, the more important it is that the procedures and protections built into modern identification techniques be carefully followed. To omit them or take shortcuts increases the

likelihood of false identification, which not only can put an innocent person in prison but also leave the actual offender on the street to offend again.

Preparation of a Police Lineup

The key concern when preparing a lineup is that the suspect should not stand out from the fillers. Eyewitnesses commonly believe that law enforcement has correctly placed the guilty person in the lineup and that their task is to choose this person. Any characteristic that uniquely differentiates the suspect from the fillers may be taken as indicating the identity of the offender. To ensure that the suspect does not stand out, a high-quality lineup will consist of fillers that are similar in appearance to the suspect. Lineups that meet this criterion have been shown to improve the accuracy of the decisions made by witnesses by decreasing the likelihood of a false identification. A variety of factors should be considered to ensure that the suspect does not stand out.

General Appearance

Faces should be similar in their overall shape (round, long, square, triangular) and have similar forehead area and hairline. The features of the fillers should resemble those of the suspect. No one in the lineup should have a facial expression that marks him or her as distinct from the others. Skin coloration should not vary widely.

Distinctive Features

If a witness reports a specific distinctive feature (e.g., marks, scars, tattoos) in his or her description of the perpetrator or if the suspect has a distinctive feature, all lineup members should have a distinctive feature consistent with that described by the witness or present on the suspect. If unable to locate fillers that share the consistent feature, it is better to add that distinctive feature to the fillers that do not have that feature (e.g., through photo editing software) rather than obscuring the feature on all lineup members.

Clothing

Clothing should either be highly consistent across all members of the lineup or should vary

widely. The clothing described by the witnesses from the original criminal event should not be worn by any member of the lineup.

Photograph Quality

Photographs should be highly similar in their general properties (e.g., color of background, source of illumination, facial shadows, contrast, clarity) and should be originals or, when using digital images, prints shown to the witness should be made directly from the digital image. Photocopies from Xerox-type copiers should not be used.

Administration of a Police Lineup

The manner in which the lineup is administered can influence the quality of the witness's identification decision. Factors found to influence these decisions include the pre-lineup admonitions provided to witnesses, the administrator knowledge of the suspect's identity, the manner in which the lineup members or photographs are presented to the witness, and the use of repeated lineups with the same witness.

Pre-lineup Admonitions

Instructions (i.e., pre-lineup admonitions) for witnesses generally influence the witnesses' perception of how much evidence of identity they require before making an identification. Because witnesses tend to approach a lineup with the expectation that the police have identified the perpetrator, they often perceive that their duty is to pick out the perpetrator rather than to evaluate the lineup to determine if the perpetrator is present. Statements made to the witness prior to viewing a lineup have been demonstrated to further exacerbate this misperception of the lineup task. For example, if the witness is told, "We've got a guy who we think did this, and we'd like you to look at some pictures to identify him," the witness has been given information that the police think they have apprehended the perpetrator and also that the witness's task is to identify the one person among those displayed whom the police believe is guilty. As a result, instructions have been developed to produce an unbiased context for the identification process. Instructions that inform the

witness that the perpetrator “may or may not” be in the lineup and that the investigation will continue regardless of their identification decision have been shown to decrease the witness’s expectation that the witness should identify someone from the lineup and reduces the likelihood of the witness identifying a lineup member. In contrast, instructions that inform the witness that the perpetrator, if present, may have changed his or her appearance increase the likelihood of the witness identifying someone.

Administrator Knowledge

Law enforcement agents with knowledge of the suspect’s identity can intentionally and inadvertently influence a witness’s decision when viewing a lineup. Witnesses viewing a lineup administered by this *knowledgeable* administrator may look to the administrator for cues of the suspect’s identity, even when those cues are not being provided by the administrator, thereby making the witness more likely to identify someone even if the suspect is not the perpetrator. To avoid this, all communication regarding the identification procedure from making the appointment to its actual implementation should be made by law enforcement agents who are *blind* to the suspect’s identity.

Lineup Presentation Format

Lineups are typically presented in some version of a simultaneous or sequential format. Simultaneous lineups involve the presentation of all lineup members to the witness at the same time with the witness being asked to determine whether any of the members is the perpetrator. Sequential lineups require the presentation of lineup members one at a time with the witness required to make a determination of whether the specific individual the witness is viewing at that time is or is not the perpetrator before being presented the next lineup member. Sequential presentation leads to a reduction in identification rates whether or not the offender is present. Overall, the accuracy of identification decisions in sequential lineups is sometimes equal to those from simultaneous lineups but not superior.

Repeated Identification Procedures and Memory Contamination

A common finding in the memory literature is the relative ease with which memories of past events can be changed by new information an individual encounters. This phenomenon is referred to as *memory contamination*. One source of memory contamination is the repeated presentation of a suspect to a witness across multiple identification procedures. Identifications made by witnesses participating in two or more identification procedures containing the same suspect are less likely to be accurate. Another source of memory contamination is postdecision feedback provided to witnesses regarding whether or not they identified the suspect. No information about witness performance should be given to witnesses by law enforcement or anyone else.

Documentation of Confidence in Identification Decision

When assessed immediately after the identification decision, a witness’s confidence in his or her decision can be a valuable indicator of the likely accuracy of that identification. Because of the ease with which witness confidence can be manipulated, certainty statements provided by a witness at any time other than immediately after the identification decision are unreliable indicators of accuracy.

Current Recommendations for Conducting Police Lineups

Evidence-based recommendations for creating and administering lineups have been specified in many policy statements, including those produced by the U.S. Department of Justice, the International Association of Chiefs of Police, the Innocence Project, the National Academy of Sciences, and various state prosecuting attorney and law enforcement organizations (e.g., Washington Association of Prosecuting Attorneys, Law Enforcement Management Institute of Texas). Although specific recommendations may vary across these organizations’ policies, four core recommendations are consistently found.

Lineup Composition

Lineup composition refers to the quality of the fillers selected for the police lineup. The suspect should not stand out among the fillers. Fillers should be selected based on their physical similarity to the suspect and should reflect the descriptions given by witnesses, providing they were clear, specific, and in agreement.

Pre-lineup Admonitions

Pre-lineup admonitions refer to the instructions provided to the witness prior to participating in the police lineup. To decrease the likelihood of a false identification, this recommendation states that witnesses should be informed that the perpetrator may or may not be in the lineup, that they are not required to make an identification, that it is just as important to exclude innocent individuals as it is to identify the perpetrator, and that the investigation will continue regardless of the witness's decision.

Blind Administration

Blind administration occurs when the law enforcement agent administering the lineup does not know which individual in the lineup is the suspect. To decrease the potential for administrators to intentionally or unintentionally influence a witness's decision, this recommendation states that the law enforcement agent presenting the lineup to the witness should not have knowledge of which individual is the suspect.

Documentation

Documentation refers to the extent to which a complete record of the lineup procedures and the witness's decision are produced. To maximize the quality of the evidence collected from the witness and decrease the potential for future information to contaminate the investigator's and witness's recollection of the lineup procedure and witness's decision, this recommendation states that law enforcement should produce a complete record of the lineup including the individuals or photographs shown to the witness, the instructions provided, any statements made to the witness during or after the lineup, and any statements made

by the witness during or after the lineup including a statement clarifying the witness's certainty in his or her identification decision. All identification procedures should be video recorded so as to show the administrator, witness, the identification materials (e.g., photos, forms), and a clear view of the surface on which the materials are placed.

Law Enforcement Practice and the Implementation of Recommendations

Various state and municipal law enforcement agencies have adopted aspects of the recommendations. Training in their implementation appears to have lagged considerably behind the formal adoption of policy, and it is not at all clear whether law enforcement agencies effectively monitor the compliance of their investigators with the new protocols.

POLICE MISCONDUCT AND CORRUPTION

Police officers hold a position of power in the criminal justice system, exercising authority over members of the public to maintain order in society. Much research in the field of criminal psychology focuses on understanding offenders and their offending, assisting police in their role of crime detection and investigation. However, research has also acknowledged that police officers themselves do not always act within the law or exercise their authority in acceptable or ethical ways. Where there is power, ultimately there is the risk of corruption, and policing is a high-risk occupation, rife with opportunities for criminal actions as well as workplace misconduct. The consequences can be far-reaching, with negative impacts on the criminal justice system including miscarriages of justice as well as reduced public support for the justice system through undermining beliefs in police legitimacy. This entry discusses types of police wrongdoing, contributing factors, and some responses.

Definitions and Measurement

Knowledge of the extent of police wrongdoing is dependent on how it is defined and measured. While some authors use the terms *corruption* and *misconduct* interchangeably, and as synonymous with generalized workplace wrongdoing, others provide more specific definitions to acknowledge and distinguish a range of unethical practices. Police officers can be vulnerable to corruption defined as acting against their duty (or failing to act in accordance with their duty) in exchange for some sort of gain. This can be considered different from misconduct, which is typically breaking the internal rules of the organization but which does not necessarily involve a relationship with a

corruptor. Finally, police officers can commit criminal offenses, the same as any member of society.

Sources of knowledge on this topic can be particularly problematic due to the secrecy of police officers and police culture more broadly, often termed the *code of silence*. This can impact the likelihood of wrongdoing coming to light as well as directly interfere with investigations. Historically, therefore, serious cases of corrupt conduct have often been revealed through whistle-blowers and media exposés, leading to large-scale investigations or commissions of inquiry. Examples include the beating of Rodney King in 1991 leading to the Christopher Commission investigation into the Los Angeles Police Department, the Fitzgerald Inquiry into corruption in the Queensland (Australia) Police after a series of media stories in 1987, and the Leveson Inquiry after the UK phone hacking scandal in 2011.

Less serious issues are often highlighted through complaints by members of the public. However, historically, the public lacked confidence in police to take such complaints seriously and investigate them impartially. This led to the establishment of independent complaint-handling bodies, some of which publicize extensive data on numbers and types of complaints received against officers in their jurisdiction. Such data, though, have been argued to represent only the *tip of the iceberg* in terms of revealing problem behavior.

Difficulties in detection of acts of corruption or misconduct have led researchers to develop alternative measures, such as ethical climate surveys. These surveys measure officers' ethical attitudes and hypothetical behavior in response to a variety of scenarios and can be used to monitor trends over time, both between and within police departments. This signifies a more research-oriented approach of monitoring issues rather than investigating individuals.

Cases and Types

Policing is not the only occupation open to corruption and misconduct, but police work offers some unique opportunities. Areas of police work involving large sums of money, such as those investigating drugs, vice, or robbery, have shown particular risks, as well as undercover police work

and dealing with criminal informants. The powers delegated to officers, and the high degree of discretion they have in applying them, mean their decision-making can be vulnerable to internal and external influences. Officers may experience implicit biases when applying the law but can also face explicit attempts at influencing their conduct. This could range from a motorist trying to avoid a speeding ticket to organized criminals looking for protection for their illegal activities, and incentives can be wide-ranging.

The Knapp Commission, which investigated corruption in the New York Police Department in the early 1970s, highlighted the difference between officers who were *meat eaters* or *grass eaters*, proactively seeking out opportunities for large-scale gain or reactively responding to offers of low-level perks, respectively. Common to both, though, was an underlying motivation of benefit for the officer. However, scholars soon recognized that officers could also act corruptly to further organization goals. The *Dirty Harry* effect saw police rule breaking under the guise of the *noble cause*, that the ends justified the means. This could include illegal searches, planting evidence on suspects, ignoring due process (e.g., questioning suspects without legal representation), and forcing or falsifying confessions. While the motivation was to solve crime by ensuring the arrest and conviction of suspects, such behavior has led to high-profile miscarriages of justice around the world, such as the cases of the Birmingham Six and Guildford Four in the United Kingdom in the 1970s.

After the 1990s, police deviance shifted from corrupt behavior toward the abuse of authority. Assault and excessive force consistently appear among the most common types of complaint against police across many jurisdictions around the world. Many scholars cite the inappropriate use of coercive force to be the central problem of police misconduct, creating a *slippery slope* toward more serious behavior such as lying and falsifying charges against the victim. This corruption–brutality relationship was noted by the Mollen Commission, which investigated the New York Police Department in 1994. The negative impact on police–community relations is also evident from high-profile public demonstrations and rioting in both the United States (e.g., in Ferguson,

MO, in 2014) and the United Kingdom (e.g., the 2011 riots in London and other UK cities) in response to police use of deadly force.

There is also increasing interest in the conduct of police officers while off duty. Clearly, police officers should not be engaging in any form of criminal behavior, but many hold police officers to higher moral standards than ordinary citizens. Activities such as secondary employment, conduct in social situations (particularly involving alcohol or other substances) or on social media, as well as associations held by police officers can all come under scrutiny. Actions that do not conform to expected standards, even when out of uniform, can reduce public perceptions of the legitimacy of police officers and damage the reputation of whole police departments.

Causes and Contributors

Inquiries and research into police wrongdoing initially promoted individual-level explanations that labeled corrupt officers as *rotten apples* in an otherwise *healthy barrel*. This quickly gained traction with police departments as it was more palatable to identify and remove individuals than to consider problems widespread and systemic. Police recruitment still relies on such a perspective to a certain extent, with procedures to screen out undesirable traits, attitudes, and backgrounds considered unsuitable for police work. However, this perspective assumes that *bad* individuals will always be bad and so can be detected early and that removal of individuals will remove the problem; neither is always the case.

Subsequently, there was a growth in recognition of the policing culture as being inherently problematic, with ethnographic and observational research concluding that all police officers share common values and norms including a sense of social isolation from, and cynicism toward, the public, solidarity with fellow officers (the code of silence), and traditional notions of masculine behavior, as well as support for the use of coercion. However, these dimensions have been criticized as a stereotyped, negative view of police, and there is debate as to whether police culture is homogenous or varied. Thus, it is not only the officer's cultural environment that is important, but how that officer responds to it. Differences in

culture are also noted at distinct phases of officers' careers and at different positional ranks.

A common finding of corruption inquiries is that certain policing structures and goals (organizational factors) can breed systemic problems and promote negative cultures that tolerate or perpetuate poor behavior. Much police work operates in an environment of low visibility, with a lack of supervision, where officers may encounter multiple opportunities to use their discretion as to whether and how they enforce the law. As noted, under these conditions, there can be opportunities for corruption, particularly in environments where large sums of money are involved. In addition to pressures from everyday encounters, the organization can contribute to problems through setting performance goals based on arrests, crime *clear up* rates, and other metrics that evaluate policing by the outcomes rather than the integrity of the process. Similarly, providing insufficient or unworkable policies and a lack of leadership to reinforce standards, oversee activities, or address behavioral issues can also promote a culture that tolerates misconduct and corruption. Early inquiries highlighted particular problems with supervisors turning a blind eye to wrongdoing or setting a bad example to junior officers through their own inappropriate behavior. Contemporary perspectives have begun to recognize the importance of supervisory behavior in terms of the fair treatment of officers and the effect this has on officers' organizational commitment and rule adherence.

Responses and Prevention

Understanding the causes of misconduct and corruption aids in designing appropriate responses and prevention strategies. Inquiries into police corruption often highlight the ineffectiveness of police internal investigations and the need for greater external accountability of police agencies. Public confidence in the impartiality of police to investigate complaints against their own officers has typically been low. It is, therefore, common for police jurisdictions to have a mechanism for civilian oversight. However, the independence and scope of such a mechanism can vary greatly from the review of police decisions, to extensive powers and resources to independently investigate suspicions of corruption. While external agencies can

provide the reassurance of independence and improve public confidence in complaint handling systems, police agencies must also take responsibility for the behavior of their employees for ambitions of police integrity to be considered genuine.

Reactive responses to misconduct include providing suitable consequences for rule breaking. This includes provision of remedial responses, such as counseling or retraining, as well as punishment and possible criminal prosecution of officers. Early intervention systems are a popular concept within police departments, whereby patterns of misconduct can be detected early through monitoring prescribed indicators, such as complaints, to identify and address problems early before they escalate in seriousness or frequency. More proactive approaches to improving behavior include applicant screening and enhanced ethics training, drug and alcohol testing of officers on duty, and risk management procedures, for example, registering gifts and conflicts of interest. Technology is also increasing police accountability. Beginning with the audio recording of police interviews to guard against false statements, now searches and seizures are routinely video recorded and, increasingly, officers are using body-worn video cameras to record their encounters on the street. Technology also helps to track police patrol cars, including during high-speed pursuits; record and control access to confidential information through individualized accounts; and provide sophisticated covert tactics for gathering intelligence on possible corrupt practices.

Finally, modern policing places more importance on the culture of integrity. Police agencies publicize their organizational goals and values, which typically include service delivery to the public, as well as ethics and fairness. These messages promote the integrity of the policing process, although there can still be some tension between these messages and numeric outcomes-based performance measures. Officers are also encouraged to come forward and report wrongdoing (indeed in some jurisdictions not doing so is a disciplinary offense) and are provided support to manage ethical dilemmas in the workplace, such as telephone advice lines.

There is a range of reactive and proactive measures that jurisdictions can adopt to improve

police behavior. Whether a minimal or more advanced approach is chosen may depend on the environment, including the opportunities for wrongdoing; there is no one-size-fits-all strategy; solutions should be tailored to problems. Police departments must be open to scrutiny, be data driven, and learn from incidents in a way that recognizes the value of external assistance in tackling problems at the systemic level.

POLICE OFFICER EVALUATIONS: SUITABILITY FOR HIRE AND FITNESS FOR DUTY

Suitability for hire and fitness for duty evaluations (FFDEs) for police officers are complex evaluations that attempt to predict one's suitability for being hired as a police officer or to determine fitness to continue to serve as an officer. There are multiple issues with regard to conducting these assessments; some of the issues addressed in this

entry are (a) predictive validity; (b) normative samples, defensiveness, and response styles; (c) the California Peace Officer Standards and Training (POST) dimensions; (d) typical problems with police officers; and (e) typical types of psychological measures that are used in conjunction with police evaluations.

Predictive Validity

Predictive validity refers to how accurate psychologists are in predicting what they are trying to predict. It asks the question, "What percentage of the time is a psychologist correct in his or her opinion about what they are trying to predict?" To improve this validity, it is important to use measures that have been shown in research to be linked to the outcome variable, in these cases, suitability or fitness. Many measures have been used in evaluations, but not all have been found in research studies to be accurate in predicting suitability or fitness. Just because a measure is useful in a clinical population, it should not be assumed that it is relevant to the issues involved in police screening. But, there is limited research on the predictive validity of common clinical tools used by psychologists for police evaluations. As a result, measures not shown in research to be predictive of suitability or fitness are often used because they are predictive of clinical syndromes and addictions.

Two ways to improve predictive validity are to use measures shown in research to be predictive of suitability or fitness and to conduct future research on the predictive validity of common clinical tools for these evaluations.

Normative Samples, Defensiveness, and Response Styles

A normative sample is a sample of individuals who have previously taken a given test. Typical sample numbers are in the thousands. An examinee's score during a suitability evaluation or FFDE is compared to the normative sample. Scores too high or too low are considered *not normative* or *outliers* because they lie outside of the typical responses in that group and are rarer for that sample. The type of normative samples used in evaluations is important because it has an

effect on whether or not the individual is being compared to individuals similar to himself or herself.

A sample of applicants who were subsequently hired, or a sample of incumbent police officers, is called a *public safety sample* and is preferable in suitability evaluations to a clinical or community sample for multiple reasons. One reason is that the American Psychological Association's ethical guidelines state that appropriate normative samples be used when conducting psychological assessments. Another reason is response styles, or an individual's tendency to deliberately try to fake good, fake bad, or respond randomly or inconsistently to items. In police evaluations, individuals are being assessed with regard to employment and not as individuals in the community seeking psychological assessment or treatment. So, when they take the tests, there may be an increased level of defensiveness, a tendency to portray oneself in a favorable light, an unwillingness to admit to minor shortcomings, or an attempt to get out of work.

Most individuals assessed for preemployment are hoping to be found suitable for the job and free from mental illness. A desire to be hired can increase the results of the validity scales. As such, a *faking good* response style can render the results invalid. For example, in a FFDE, an individual could fake bad or fake good, depending on their motivation (i.e., wants to get out of work or wants to go back to work, respectively).

Using public safety samples in suitability evaluations can minimize the likelihood that measures will be invalidated because of defensiveness or a tendency to fake good in suitability evaluations. This is because the entire normative sample was assessed for preemployment reasons rather than for a clinical reason or for participation in a study. Therefore, in suitability evaluations, the tendency to fake good would likely be the *norm* because candidates will want to be seen as suitable. The use of a public safety sample serves to normalize a tendency to portray oneself in a positive light. Thus, because most candidates in suitability evaluations want to be hired, the use of public safety norms helps to level the playing field. As a result, a candidate would have to be extreme in his or her attempt to fake good in order for the validity scale to be considered significant.

Using a public safety sample also helps to detect pathology that may have been missed if an individual was portraying himself or herself in a positive light, but not to the extent that the measure would be invalidated. In those cases, the scales assessing for pathology would be reduced, and there would be a greater likelihood the psychologist would not see problems when looking at the data. This is because the scale that assesses for various dimensions would be depressed or subthreshold and not flagged as a problem. Thus, when possible, it is preferable to use measures that offer a public safety normative sample when conducting suitability evaluations. To date, no FFDE normative samples have been developed.

California POST Dimensions

The California POST dimensions provide a well-researched and defined taxonomy for defining suitability. The California POST Commission conducted a statewide analysis of the demands and requirements of the job through subject matter experts (patrol supervisors and field training officers) from the entire state of California, rating the importance of various competencies to successful officer performance. After three empirical studies, the following 10 dimensions were found consistently to be linked to successful performance:

1. *Social competence* involves social awareness, empathy, respectful communication, and concern in one's daily interactions.
2. *Adaptability–flexibility* involves the ability to adjust to unexpected or sudden tasks and the continuation of duties without supervision.
3. *Impulse control–attention to safety* involves the avoidance of unnecessarily risky and/or impulsive behavior, attention and awareness of hazards, and ability to suppress impetuosity.
4. *Teamwork* includes effectiveness in working with others, providing assistance, and maintaining cooperative working relationships.
5. *Conscientiousness–dependability* involves reliable and diligent work patterns, carrying out assigned tasks, good organizational skills, and perseverance.

6. *Integrity–ethics* involves maintaining high standards of personal conduct, abiding by laws and procedures, and not bending rules or abusing the system for a personal gain.
7. *Avoiding substance abuse and other risk-taking behavior* involves avoiding participation in risky behavior that can be self-damaging or inappropriate (e.g., sale of drugs, domestic violence, alcohol or drug abuse).
8. *Emotional regulation and stress tolerance* involves the ability to stay in control and maintain composure in stressful situations, acceptance of mistakes, and maintaining an even temperament on and off duty.
9. *Assertiveness–persuasiveness* involves taking control appropriately in all situations, the ability to confront suspects, and persuading others to adopt a desired course of action.
10. *Decision-making and judgment* involves the ability to use practical judgment and efficient problem-solving skills, and the application of deductive and inductive reasoning when necessary.

Typical Problems With Police Officers

While the POST dimensions are used to define the *ideal* cop, they are dynamic rather than static variables, meaning that they do not remain fixed but instead can change over the course of a career as critical incidents or other events occur. Once an officer is found suitable for hire, he or she may encounter problems, experience trauma, or other circumstances may arise that may render that officer unfit. Typically, police departments will identify a problem and refer the officer for an FFDE. Reasons for referral of an officer for examination typically fall into four main categories: (1) trauma and post-traumatic stress disorder, (2) substance abuse problems, (3) domestic violence or anger management problems, and (4) other.

Due to the circumstances of the job and the role of being a first responder, police officers often experience work-related trauma. Some officers also have substance use disorders, either as a coping mechanism for post-traumatic stress disorder or for other reasons. It is more common for alcohol use to be problematic than street drugs, as

officers are randomly drug tested. However, officers who have had work-related injuries may become addicted to prescribed medications.

Difficulties in managing anger and relationships can also arise for police officers. Long hours, night shifts, a need to maintain control and order at work, and pent-up anger can result in domestic violence and anger management issues. Finally, there are a number of *other* situations, such as those related to off- or on-duty misconduct, head traumas, dementias, concussions, brain diseases, grief, stress, or other medical illnesses that can affect one's mental state.

Typical Assessments and Measures

Psychological testing for preemployment screening typically involves a measure of normal personality traits such as the Big Five: conscientiousness, emotional stability, agreeableness, extraversion, and openness. The California Personality Inventory looks at the Big Five traits as well as others. The factor scales of the California Personality Inventory have been researched and shown to be valid predictors of the California POST dimensions. Public safety norms are also available for the test. The Public Safety Report offers favorable and unfavorable job indicators related to fitness as well as information about job suitability.

Also, typically administered in suitability evaluations is a screen for psychopathology and substance abuse. The Personality Assessment Inventory–Public Safety Selection Report and the Minnesota Multiphasic Personality Inventory–Restructured Form–Police Candidate Interpretive Report are designed to detect pathology and substance use disorders. Both measures provide public safety norms and information regarding job suitability.

In suitability evaluations, a measure of cognitive functioning is also typically given to ensure adequate cognitive functioning. The choice of cognitive measures depends on the purpose of the testing. For instance, in a preemployment examination, in which multiple applicants might need to be assessed cognitively, a group-administered measure that provides a quick cognitive screening can be administered. However, if the individual is already a police officer and has a head trauma or possible dementia, full testing with a comprehensive IQ test or the use

of neuropsychological measures might be indicated in order to answer the question of fitness.

Various other measures are often used to assess background history, substance abuse, violence risk, suicide risk, current stressors, coping abilities, and state or trait anger. Most of the measures that are used in FFDEs have no public safety norms and have not been shown to have predictive validity. Many of the clinical measures, however, do have predictive validity with regard to the individual problems or mental health disorders assessed.

POLICE RESPONSE TO PEOPLE WITH MENTAL ILLNESS

During the last third of the 20th century, dramatic changes in regard to the treatment of people with mental illnesses occurred. In particular, the development of antipsychotic medications meant that many people, particularly with psychotic illnesses such as schizophrenia and bipolar disorder, who had formerly been untreatable, were now able to receive medical treatment that effectively reduced many of their symptoms. At the same time, changes in mental health legislation resulted in an increase in the rights and privileges accorded to people with such problems. In combination, these factors resulted in significant numbers of people with mental illnesses being discharged from psychiatric hospitals and, thus, living in the community. This contributed to a substantial increase in the number of interactions between police and people with mental illnesses. Since that time, police organizations have been developing a number of initiatives and programs to address this situation.

Nature and Causes of Police Interactions With People With Mental Illnesses

While on the surface these major shifts were advantageous to people living with mental illnesses, there were a number of unforeseen consequences from this mass deinstitutionalization. In most countries, governments did not anticipate or provide sufficient support for people with mental illnesses living in the community. Inevitably, this led to an increase in the involvement of people with mental illnesses with the criminal justice system in general and, in particular, a dramatic increase in the number of interactions between people with mental illnesses and police.

Although reliable data are difficult to come by, it has been estimated that 7–15% of police calls might involve a person with a mental illness or a mental health problem. The question of whether people with mental illnesses are actually more likely than other people to participate in criminal activity is complex. There is evidence that mental illness in combination with substance abuse can lead to an increase in criminal activity. However, it does not appear that an increase in criminal activity by people with mental illnesses is the primary reason for the increased number of interactions between police and people with mental illnesses. In fact, most interactions between police and people with mental illnesses do not involve criminal activity. There are a variety of reasons why PMI might come in contact with the police:

- most mental health legislation includes a provision for police to apprehend people who appear to be experiencing a mental illness under certain conditions and take them to a psychiatric facility for assessment; this usually occurs in situations in which the person is perceived to be a danger to him- or herself or to someone else;
- people with mental illnesses, particularly when they are unwell, are at higher risk to become victims of crime and, therefore, might come in contact with the police when they have been victimized as opposed to being perpetrators of crime;
- people with mental illnesses are at much higher risk of becoming homeless;
- the families of persons with mental illnesses often resort to calling the police when their relative appears unwell and in need of treatment, but the person with mental illness might not be agreeable to going voluntarily to the hospital to receive such treatment; hence, police might use the authority of mental health legislation to take such persons involuntarily;
- police might, and indeed often do, play an informal social support role with people with mental illnesses, informally keeping track of them and looking out for their well-being; and
- some people with mental illnesses do in fact participate in criminal behavior and come to the attention of police in this context.

Because of the often inadequate mental health services, many people with mental illnesses have their first contact with the mental health system through the criminal justice system. Police can even be viewed as the gateway to the mental health system for persons with mental illness or mental health problems.

Even though attending to vulnerable populations, such as those with mental health problems, is an integral part of police work and consistent with the fundamental principles of contemporary policing, the involvement of the police might also contribute to undue stigmatization of mental illnesses. In addition, police have traditionally not been well equipped with the skills and knowledge necessary to interact constructively with people who might be acutely ill. This can be due to several reasons. One is that sometimes police officers are hired who are not suitable for some aspects of police work. Another is that sometimes basic training of new police officers as well as ongoing in-service education and training is insufficient to prepare police personnel for working with vulnerable persons. As a result, some interactions have not gone well.

When one looks at statistics related to use of force by police and their interactions with the public that result in a death, people with mental illnesses are clearly overrepresented. Consequently, starting in the mid-1990s, there has been increased emphasis within police agencies and police academies to develop skills and knowledge on the part of police officers to understand and interact with people with mental illnesses and to form greater and more constructive linkages with the mental health system.

There have been two areas of particular focus in regard to improving outcomes of police interactions with people with mental illness. The first of these has related to providing not only additional education and training for police personnel but also a wider variety of education and training that will enable positive outcomes. The second relates to the development of specialized teams and services within police agencies to respond to calls for service that might involve a person with a mental illness.

Education and Training for Police Personnel

By the early 21st century, it had become fairly standard for police academies to include at least a

minimal number of hours of training and education about mental illness for police officer candidates. Typically, such curricula include the following:

- understanding the basic signs and symptoms of mental illness,
- the common types of mental health diagnoses and treatments,
- assessing and responding to suicidal people,
- verbal interaction and de-escalation skills,
- the powers and limits accorded to police under mental health legislation, and
- the options available to police when they encounter a person who appears to have a mental illness.

While some research has been conducted in regard to police interactions with people with mental illnesses and the learning necessary to maximize positive outcomes, overall, substantial additional research is required. In particular, research that is focused on how effective current learning programs are and how learning will be retained by police officers over time and applied under sometimes stressful circumstances is necessary. The extant research in regard to the efficacy of such education and training is inconclusive, as it can be difficult to determine exactly what components are most effective in changing police behavior. Moreover, it is also difficult to measure actual changes in behavior. In addition, curricula are highly variable from one police academy or organization to another. Many studies report an improvement in knowledge and attitudes on the part of police following training. Nevertheless, it has become generally recognized that education and training in this area should be multifaceted and ongoing, and needs to focus on a variety of factors including stigmatizing attitudes, factual knowledge, skill acquisition, and active problem-solving.

One comprehensive contemporary framework that has been developed by the Mental Health Commission of Canada and supported by the Canadian Association of Chiefs of Police is *TEMPO*, an acronym for “Training and Education about Mental Illness for Police Organizations.” It reflects a multilevel and continuing education focus for all personnel of a police organization, including not only police officers but

also personnel such as call takers, dispatch personnel, and victim service workers.

TEMPO, in part, draws on the foundations from Crisis Intervention Teams (CITs, described in the next section) as well as the international literature and a review of the various curricula used in police academies in many different countries and jurisdictions. In addition to knowledge and skills, it focuses on active problem-solving, addressing stigma, ethical conduct, human rights, and utilizing a systems approach to interactions with people with mental illnesses. Overall, it emphasizes that design and delivery of police learning must be in conjunction with persons with mental health problems.

Police Response Models

While education is an essential component for the preparation of police for successful interactions with people with mental illness, there is also a need for specific program and service delivery developments—appropriate response modes. Probably the most well-known and well-researched police-based response model is the CIT, often referred to as the *Memphis model* since it originated in Memphis, TN. This is arguably the predominant model in the United States. Its focus is on developing a critical mass of highly skilled and specially trained police officers within a police agency who serve as resources to other police first responders.

When a patrol officer encounters a situation involving a person with a mental illness, the officer is able to contact a member of the CIT who can assist in the resolution of the situation. These specialized officers have received extensive training about mental illness and are also involved in developing liaisons with the mental health services in their jurisdiction. A key component of the CIT model is the formation of alliances between specific mental health services and the police organization, so that police have options and resources that might assist them in dealing with situations involving persons with mental illnesses when neither hospitalization nor criminal charges are appropriate.

However, the CIT police-based response model is not the only response model designed to work with people with mental illnesses. In some

jurisdictions, co-response models are more common. There are varying forms of co-response models, but the essential feature of these models is that a police officer and a mental health worker (who might be a nurse, a social worker, a psychologist, or other mental health worker) respond jointly to calls involving a person who appears to have a mental illness. In Canada, co-response models are the predominant model. It has been hypothesized that one reason for this is that the lower overall rate of violence in Canada leads to a perception that it is safer for mental health personnel to be directly involved at the time of first response.

Co-response models might take a variety of forms. In some instances, the teams are first responders and respond directly to calls that appear to involve a person with mental illness, whereas in other cases, they might provide a secondary response after the initial response by a patrol officer. Co-response models might be based in either a police organization or a mental health organization with personnel from one organization being seconded to the other. This type of model also helps to deal with the barrier that often prohibits information sharing between police and mental health agencies and, therefore, might result in more effective disposition of individual situations.

Because of the variability of the different co-response models, it is difficult to assess their efficacy and to compare them with CIT-type responses. There is evidence that both of these response models tend to reduce the number of apprehensions of people with mental illnesses by police pursuant to mental health legislation as well as arrests for apparent criminal behavior. There is some evidence that officers who have received CIT training might resort to less use of force in their interactions. There is also some evidence that there is an increased number of linkages between people with mental illnesses and mental health agencies when CIT officers are involved. Similarly, a review of co-response approaches indicates a variety of positive outcomes, including an increased number of linkages with the mental health system, a decrease in the number of hospital admissions, and a decrease in the amount of time that police spend in their interactions with people with mental illness. Some studies have also indicated that such models are cost-effective overall.

A few larger police agencies have also developed case management processes for people with mental illnesses, whereby particular individuals who tend to be heavy users of police resources are the focus of individualized case management plans developed jointly by the police organization and its partner mental health agency as well as appropriate social agencies. This type of service is often useful and effective in community management of individuals with severe personality disorders.

Police-based programs to address the needs of people with mental illnesses often—and ideally—work in conjunction with other community programs such as mental health system-based crisis line and crisis services, mental health courts, other diversion programs, social services, and hospital-based services including emergency rooms and psychiatric facilities.

The Strategic Approach

While all of the aforementioned approaches appear to be promising and there are data that support their effectiveness to some extent, it has become increasingly apparent that the mere presence of an add-on program or specialized team within the police agency is not sufficient to address the many and complex problems identified earlier that might involve vulnerable people including those with mental illnesses. In addition, while such programs might be cost-effective and practical in larger jurisdictions, smaller towns and cities as well as more rural jurisdictions are not likely to be able to support such specialized programs given the relatively smaller number of calls that might involve people with mental illnesses. Therefore, since about 2012, there has been an increasing tendency for police agencies to consider the development of a comprehensive strategic approach to address the complex needs of vulnerable people, in general, and people with mental illnesses in particular.

A strategy, as opposed to a discrete program, includes an emphasis on the root causes of problems as opposed to focusing predominantly on the symptoms of a problem. In the case of police interactions with people with mental illness, a strategy is likely to reflect the need for an organizational culture that reduces or eliminates stigma related to mental illness and focuses on human rights, procedural justice, and

reduction of criminalization. Typically, such a strategy would focus on increasing the likelihood that interactions between police and people with mental illnesses result in positive outcomes; that police are part of a comprehensive community system involving government and nongovernmental organizations including not only health and mental health organizations but also those that support housing, income education, and employment; that approaches to interactions with persons with mental illness reflect not only the mental health needs of the individual but are also needs specific to gender, culture, language, and local community needs; and, arguably most important, that police interventions are both proactive and reactive.

Of note is that a strategy includes and directs the need for the development of appropriate educational initiatives and specific programs, but goes beyond that and recognizes that police might interact with people with mental illnesses in a wide range of circumstances, and that, therefore, no single stand-alone program will address all possible circumstances. As of 2015, very few police organizations were taking a strategic approach; however, it appears that the Los Angeles Police Department is one police agency that takes such an approach. The Ontario Provincial Police, Canada, have recently developed a comprehensive strategy to address not only their interactions with people with mental illnesses but also the mental wellness and understanding of mental health in the police workplace. These are both bold initiatives that could be emulated in the interest of improving outcomes for persons who have mental health problems within as well as external to a police organization.

POLICE SUICIDE

The Centers for Disease Control and Prevention estimates that 30,000 people die by suicide in the United States each year. The topic of suicide by law enforcement officers prompts controversy among those in the mental health and law enforcement communities, as questions of cause and influence come into play. Some experts claim that a breakdown in relationships is what leads to suicide among officers. Others argue that it is the

inherent stressors of the job that breaks down an officer's resilience and adaptive coping resources, which in turn leads the officer to take his or her own life. In this entry, several issues that may contribute to police suicide are considered.

Although the media portrays high numbers of suicide within law enforcement, some researchers dispute these numbers. Some studies have indicated that the number of law enforcement suicides may actually be lower than those of the general population when the sample is matched according to gender, age, and race.

Repeated Exposure to Trauma

Police suicide started receiving recognition in the 1990s. Studies were conducted by various recognized police psychologist experts working in partnerships with federal agencies to understand why police officers who are charged with helping their communities live better lives were taking their own lives after years of service. Officers often choose their profession out of a motivation to help others; however, within the first 5–10 years, they often report burnout, a perception that their ability to help others has decreased and witnessing continuous tragic events can lead up to cumulative stress. Vicariously experiencing other peoples' pain is a daily part of law enforcement and, as many remain in law enforcement until retirement, this daily experiencing of others' hardships continues for years. Being a part of these critical incidents can start to alter their own moral perspective as a result of regularly seeing the negative side of society. While officers wear body armor to protect their physical well-being, they often also develop internal armor that protects their psychological well-being. To those who lack understanding of the true job requirements, it can appear that the officers are cold, insensitive, distant, unyielding, uncaring, or overbearing—perceptions that can impact interpersonal relationship dynamics.

Family and Relationship Challenges

When an officer finds it difficult to cope with vicarious trauma, he or she may choose maladaptive behaviors such as alcohol abuse, extramarital affairs, or pulling physically and/or emotionally away from the home environment. Another cited

relationship challenge is the physical absence of the officer from the family, due to the requirements of the job. As a consequence, the officer's spouse becomes, by default, the primary manager of the home and parental figure for the children. This situation can cause stress on all family members, which can lead to marital discord.

Another cited challenge is the difficulty an officer may have in effectively communicating with his or her spouse; the tendency to *protect* the loved ones by sheltering them from the horrific events *out there* may be perceived by the spouse as refusal to connect and interact honestly and vulnerably. In addition, the loved ones may have to take a back seat to the needs of the agency, for example, the officer not being available for holidays, important family events, and the daily needs of the partner and children. As the family starts to disintegrate, the officer may start experiencing some mental health issues such as depression and anxiety. However, many officers do not seek mental health services unless they are mandated to do so, such as following a particularly traumatic critical incident.

Cumulative Stress

Critical incidents or cumulative stress can start to compound and the officer who is charged to take care of others may forget to safeguard his or her own mental health, seek assistance from professionals, or speak to his or her agency. Compounded by irregular sleep schedules, competing demands, and health issues that are often neglected can lead the officer into a downward spiral. Post-traumatic stress disorder can lead the officer into poor decision-making such as drinking too much, excessive gambling, or other behaviors that can negatively impact lives and families.

Sleep disruption, including shift work sleep disorder, is common for active-duty officers. Both a lack of sleep and a disruption in circadian rhythms have been linked to issues with depression.

Following an officer suicide, it is not uncommon for family members and even other police officers to express a lack of surprise, but then in retrospect recognize some of the symptoms leading up the suicide. Moreover, it is known that veteran officers who are facing retirement are also facing the loss of an identity: no longer being active police

officers. This loss of a sense of identity, combined with a loss of sense of purpose, may contribute to retired officers' taking their own lives.

Stigma in Seeking Help

Many in the community at large are hesitant to seek mental health care due to fear of the perceived negative stereotypes involved. This perceived stigma may be even more pronounced in the law enforcement community, where an officer's ability to perform job duties hinges in part on being perceived as capable, strong, and in control. Therefore, when an officer experiences human suffering, disaster, or tragedy, he or she may feel obligated to get *squared away* (i.e., become in control physically and emotionally) without any outside assistance—especially from professional mental health services.

Law enforcement is a high-risk job in which officers are likely to witness horrific events on a regular basis. However, unlike other high-risk jobs that also involve the experience of tragedy (e.g., firefighters), officers today may be vilified by some members of the public and of the media. This can cause stress not only to the officer but also to the officer's family.

All of the aforementioned issues are just some of the potential triggers that could lead an officer to take his or her own life. Although there is disagreement in the professional communities as to the frequency of police suicide, and the direct causal factors, there is general consensus on the need for increased and improved mental health and social support resources to help reduce or eliminate police suicide.

POLICE–PROBATION PARTNERSHIPS

In 2013, a study conducted by the Council of State Governments Justice Center revealed one in five arrests in four California cities involved an individual under community supervision. In fact, many large cities have found that a substantial proportion of crimes involve probationers (either as perpetrators or victims), necessitating the increased collaboration between police and probation. This entry discusses the origins of partnerships between law enforcement and probation agencies, their various forms and functions, what is known from the available research, and the direction of partnerships going forward.

Origins of Partnership

Boston's Operation Night Light, a component within a larger multiagency initiative known as *Operation Ceasefire*, is considered the first

formalized police–probation partnership, officially established in 1992. Faced with a growing street-level gang pandemic, the partnership took root when two probation officers and two police officers had a chance encounter in court. With the realization they were both working with many of the same individuals on the street, the officers began conducting joint patrols of high-crime areas and high-risk individuals. The program operated by selecting 10–15 of the most high-risk gang-affiliated youth under supervision and performing home, school, or workplace visits in an unmarked cruiser with plain-clothed probation and police officers. In addition to targeted visits, the officers conducted patrols through hot spot locations. One of the unique aspects of Operation Night Light was the shift in the probation officers' schedules to conduct home visits between 7:00 p.m. and midnight, when youth were known to be at greater risk of criminal involvement. This required greater flexibility from the probation officers who had historically worked an 8–5 shift. Police officers that participated in the program gained a greater understanding of who was under supervision and therefore continued to operate as additional eyes for probation even when doing their routine patrols.

Operation Night Light was well received by practitioners and was quickly replicated in numerous other jurisdictions across the United States under a variety of names including San Bernardino's Nightlight, Minneapolis's Anti-Violence Initiative, Washington State's Smart Partners, St. Louis's Nightwatch, Maricopa County's Neighborhood Probation, Texas's Project Spotlight, and Philadelphia's Youth Violence Reduction Partnership.

Forms and Functions of Partnerships

Partnerships between police and probation have been categorized as serving various needs and purposes beyond those made famous by Operation Night Light and its many replications, best regarded as enhanced supervision programs. They may be larger in scope including partnerships with community and faith-based organizations (i.e., interagency problem-solving partnerships), specific to a given type of probationer such as sex offenders or perpetrators of domestic violence (i.e., specialized enforcement partnerships),

focused on the reacquisition of absconders (i.e., fugitive apprehension partnerships), or simply concern the improved sharing of information between probation and law enforcement.

Enhanced supervision partnerships, such as those discussed previously, are generally the most intensive form of partnership, requiring direct contact between police, probation officers, and probation supervisees. Characterized most by their use of joint patrols and home visits at unconventional hours, enhanced supervision has been utilized for both adult and juvenile populations, especially gang-involved youth and young adults. Ideally, such intensive programming would be reserved for those individuals at greatest risk to reoffend, but in practice, it has been used with a wide range of clientele including status offenders.

Similar to the promulgation of enhanced supervision partnerships, the development of large multi-agency initiatives has also become increasingly more common since the inception of Boston's Operation Ceasefire. These initiatives may involve numerous organizations in addition to police and probation, with the partnership between law enforcement and probation officers playing a minor role. Examples include the Boston Reentry Initiative, Pittsburgh's One Vision One Life, and Chicago's Project Safe Neighborhoods. These collaborations are characterized by several key components including offender notification forums, increased penalties for gun possession, increased federal penalties, and increased gun seizures. Offender notification forums involve the selection of a small number of high-risk gang-involved individuals under supervision who are invited to a meeting in which criminal justice professionals (e.g., prosecutors, police officers, probation officers) provide a message of deterrence (i.e., the penalties for criminal activity will be stiff) but also an opportunity to meet with community- and faith-based organizations about resources available to assist them.

Specialized enforcement partnerships are the least discussed in the literature. That said, they may comprise an enhanced supervision partnership or a larger interagency initiative that focuses on a specific group of offenders (e.g., gang members, sex offenders). Alternatively, such partnerships may be specific to a given type of criminal activity

identified by a community in need of intervention. For example, violence interrupters represent former gang members who attempt to intervene in local street gang conflicts in coordination with law enforcement and probation agencies.

Fugitive apprehension partnerships target absconders, individuals who have failed to appear before their supervising officer. Similar to when an individual fails to appear in court, a warrant will be issued for their arrest. Partnerships between police and probation in this regard are designed to expedite the arrest and return of the missing probationers, an action that otherwise would be reactionary as opposed to proactively pursued by law enforcement. Examples of these partnerships include the Fugitive Recovery Enforcement in San Francisco and the Fugitive Apprehension Program in Minneapolis.

Information sharing can be very broad and may include simply a phone call between two officers across departments, but it can also be systematic and complex. Although information sharing is embedded innately with any of the partnership types discussed, examples of advanced forms of information sharing include the Federal Bureau of Investigation's Law Enforcement Data Exchange and the American Probation and Parole Association's Offender Transfer Notification Service. Law Enforcement Data Exchange is a free national data-sharing system made available to criminal justice agencies containing information on offenders of interest. The system includes participation from community supervision agencies in addition to law enforcement. Offender Transfer Notification Service, utilizing data provided by the Interstate Commission for Adult Offender Supervision, represents the notification of state fusion centers and local law enforcement about potentially dangerous adult probationers or parolees relocating across state lines.

While formalized partnerships did not develop until the early 1990s, police–probation partnerships have in fact existed informally for decades. The key distinction is that informal partnerships rely on individual relationships between officers whereas formalized partnerships involve explicit agreements between organizations (e.g., memoranda of understanding). A key issue voiced against the reliance on informal partnerships has been the lack of succession planning and inability

to measure their impact. In other words, once a key individual transfers, is promoted, or otherwise leaves the organization, the partnership will likely vanish with the individual.

Research on Partnerships

Despite their popularity among criminal justice professionals, police–probation partnerships have rarely been formally evaluated, often regarded as a *promising practice*, short of *evidence-based*. What little research does exist has either proven to be inconclusive or, at best, shows a very slight deterrent effect on crime trends. The need for further research in this area, specific to partnerships between law enforcement and probation agencies, has been reiterated greatly in the empirical literature. Their many forms and permutations have also made it difficult to make program comparisons across jurisdictions.

Although outcome research is lacking, there has been a noticeable effort placed on gathering the input and perceptions of officers working in various partnerships. Often qualitative in nature, researchers have discovered several concerns that permeate discussions of partnerships, including mission distortion, turfism, stalking horse incidents, and organizational lag.

Mission distortion refers to the dual roles of probation as both an enforcer of probationers' conditions of supervision and a social work orientation with the goal of rehabilitation and treatment. Some have voiced concerns that partnerships with law enforcement may lead probation agencies to skew too far toward compliance enforcement, neglecting their rehabilitative goals.

Turfism refers to the competition between local government agencies to receive funding support or maintain control of their jurisdiction. One criticism of law enforcement has been their tendency to dominate partnerships or bring in organizations after a strategy has already been developed. Such rigidity can be off-putting to other organizations, including probation.

Stalking horse incidents concern the legalistic implications of police utilizing probation (or parole) partners as a means to access a person or their residence without a warrant or probable cause. Although probationers (and parolees) forfeit their right to be free of unreasonable searches

from their supervising officer, it does not necessarily extend to the purview of law enforcement officers. Several legal reviews have shown that state statutes and case law vary in regard to the permissiveness of law enforcement searches of probationers (or parolees) without a warrant. The U.S. Supreme Court has acknowledged that probationers have a greater expectation of privacy than that of parolees, but the full breadth of their protections in relation to free citizens remains unclear. That said, police officers who possess and can articulate a *reasonable suspicion* of criminal wrongdoing in which the individual is a known probationer or parolee have been successful in averting legal challenges to conducting warrantless searches of this nature.

Finally, multiple qualitative studies involving interviews with police and probation officers have revealed that leadership support is the most important component needed for a successful partnership. In essence, if the police chief or chief probation officer does not share an invested interest in the partnership, then the initiative was unlikely to develop in any meaningful way.

Despite the potential problems associated with partnerships, many practitioners have noted several benefits inherent in interagency collaboration. One example includes the added safety and security provided by law enforcement, particularly important in jurisdictions where probation officers are unarmed and conducting home visits of high-risk individuals. Furthermore, some have noted that the presence of law enforcement can further legitimize the authority of the probation officer by demonstrating that police are aware of them and their probationary status. As such, police can be more proactive in the supervision of probationers on the street. Although the impact of partnerships on probationer outcomes remains unclear, officers have reportedly formed a greater appreciation of each other's role in the larger criminal justice process as a result of their increased collaboration.

Future of Partnerships

Police–probation partnerships grew rapidly in prominence in 1990s, but by the mid-2000s, federal funding had waned in part due to the economic recession. The growth of partnerships essentially stalled. While interest in partnerships

still exists and many have continued informally at the local level, the push for formalization has ceased and federal efforts have since focused on larger multiagency initiatives. Nonetheless, practitioners remain concerned about the legal implications of police–probation partnerships, while seeing numerous benefits and recognizing the need for continued coordination. Likewise, researchers remain interested in the potential impact of these partnerships and their appropriateness to a given population of probationers or parolees.

POLICING

Policing is the act of providing security within a territory through enforcement of its laws or rules. In public policing, law enforcement agencies provide security not only through enforcing laws but also by responding to threats to public safety. Policing and criminal psychology overlap in that the focus of efforts within both fields is often the same people: individuals who come into conflict with the law for a variety of personal, interpersonal, mental health, and other reasons. After providing an overview of policing, this entry discusses various aspects of policing, including police duties, powers, and strategies.

Policing Overview

The term *police* broadly refers to public and private actors whose primary responsibility is the provision of security. It used to be said that what makes public policing different from other groups, including private security, is that the public police occupy a unique position due to their ability to lawfully use force to execute their duties. As of 2017, this is no longer the case, as legislation in some U.S. states now permits citizens the use of lawful force to stop or prevent crimes, including the use of lethal force. What does continue to mark public policing as different from private forms of policing is an emphasis on democratic accountability. As public agencies, law enforcement officials are governed under legislation, which makes them accountable to the communities they serve. In contrast, private policing is largely a commercial enterprise, and many security companies operate within states with few regulations and little external oversight.

It is important to also note here a third category of policing: military policing. Military police are responsible for law enforcement under both state and federal codes, as well as military codes of justice. They operate under the military system of justice, which runs parallel to the regular criminal justice system with its own courts and court officials. While each of these branches of policing are worthy of discussion, the focus for the remainder of this entry is on public policing and what is viewed as conventional law enforcement.

Principal Duties

The duties of police officers are set out in legislation. Because laws vary within and across countries, there may be some differences in terms of the principal functions of any given police agency; however, it is widely accepted that the main duties of a police officer include the following:

- preserving the peace and public safety
- preventing crimes and other offenses
- assisting victims of crime
- investigating crimes
- apprehending criminals
- laying charges or recommending charges to prosecutors
- participating in prosecutions
- executing warrants

While this list may seem fairly exhaustive, it does not include many other functions that police frequently assume within communities. As one of the few 24-hour public service providers, police officers often adopt a number of additional roles and tasks. For instance, police officers may be called upon to serve as *street corner psychologists*, listening empathetically to the personal or interpersonal problems of individuals in distress or with few social supports. One such example of this scenario occurred recently in the United Kingdom when police officers were dispatched to a 9-9-9 call (the UK version of a 9-1-1 emergency call) placed by two elderly citizens who were lonely and feeling isolated. Once assured that the couple were fine, the officers brewed some tea and stayed for a visit. Police also often take on tasks that are referred to as forms of social work, including helping people find shelter beds and responding to mental health calls to assist people in finding emergency health services.

Police Powers

As noted earlier, a fundamental component of the police role is the legal authority to use force to prevent or stop the commission of a crime. While this police power draws much media attention, it is only one of several legal powers invested in police for the purpose of fulfilling their duties. Other police powers include the powers of arrest, detention, and search and seizure as well as the ability of police to exercise discretion.

Police powers of arrest are generally set out in state or federal criminal statutes, which allow for two types of arrest: with and without a warrant. If a warrant of arrest has been issued for an individual, police are generally *duty bound* to immediately execute that warrant by taking the person into custody. There are, however, situations in which an individual can and will be arrested without a warrant. These vary by jurisdiction but typically include situations in which the individual is caught in the act of committing a serious offense. When the law or the circumstances of a crime do not require immediate arrest, police may appear before a judge or justice of the peace to ask for an arrest warrant to be issued.

Police officers also have the ability to place someone under temporary detention. Detentions occur when police are investigating a crime or possible crime and believe that an individual may be a witness or suspect required for questioning.

Police can also effect searches—of persons, places, and things—as well as seize items as evidence or to prevent the continuation of an offense. There are typically three ways in which police can effect a search and/or seizure: with a search warrant, upon an individual's arrest, and with the person's consent. In relation to the first option, a judge or justice of the peace has signed a search warrant or seizure order that directs police to a specific place to look for particular items believed to be associated with a crime. Police can also lawfully search an individual when the individual is arrested; in fact, this is a standard part of the arrest process. This search allows police to identify and inventory items that may be evidence of a crime, as well as reduce any safety risks associated with transporting someone who might be carrying weapons or drugs. The third method—with consent—simply involves police asking individuals if they can search the individuals or their belongings (“Can I have a look in your bag?”) and gaining a positive response.

Police use of force is governed by law, which limits the ability of police to use physical force to only those situations in which they need to carry out a duty (e.g., effecting an arrest, preserving the peace) or to protect themselves or others from risk of harm. Both police training and law emphasize that force used must be reasonable under the circumstances.

Discretion is the ability of police officers to choose between different available options—such as whether to issue a ticket to a speeder or to let the speeder off with a warning. Although discretion is not an official police power in the same sense as the power of arrest—that is, governed by law—it is a power and one that is vital to the functioning of the criminal justice system. Simply put, if police did not exercise discretion, the volume of tickets issued and cases processed through the juvenile and adult criminal justice systems would overwhelm the police, courts, and jails within a short period of time. There are, however, limits on police discretion. This entry has already mentioned one such limit: the existence of an arrest warrant. Other limits on discretion include policies established by police organizations (*ticket all speeders*). The effects of local culture and situational factors can also play a role in influencing officer decision-making. For example, in a particular community in which nearly one quarter of the population had an active addiction, police routinely confiscated drugs and drug paraphernalia but rarely arrested drug offenders for possession. Similar practices in another community may be highly frowned upon by lawmakers and community members alike.

Varieties of Public Policing: Patrol, Investigation, and Specialized Units

Generally speaking, policing tasks and roles can be divided into one of three functions within police organizations: patrol, investigation, and specialized units. Of these, patrol is the one most frequently encountered by the public in real life. Patrol officers, sometimes referred to as *the front-line*, are individuals tasked with responding to calls for service, engaging in preventive crime efforts, and otherwise patrolling the streets. Patrol officers can be deployed in cars, on foot (referred to as *walking a beat*), and on bicycles and motorcycles. Patrol officers are viewed within their organizations as generalists, meaning they must deal with a wide variety of different types of people, events, and issues.

Although the public is more likely to see patrol officers performing their duties, media attention is overwhelmingly focused on police investigators. Police investigators are experienced patrol officers

who have received specialized training in one or more areas of police investigation. Although investigation unit names and makeup vary by police organization, this work typically covers the investigation of crimes such as homicide, sexual offenses, robbery, financial crimes, among others.

Given the diverse nature of policing, officers are frequently called upon to take on a number of tasks outside of regular patrol or investigative work. As a result, many police organizations also contain specialized units that perform very specific functions. Included in this group are armed response teams, internal affairs investigators, marine patrol, dog and mounted patrol squads, gang units, among others.

Policing Strategies

Since the 1990s, a number of policing strategies have been developed, most primarily oriented toward helping police more effectively and efficiently respond to crime within local communities. This section takes a brief look at three popular strategies: community policing, intelligence-led policing, and evidence-based policing.

Developed largely through 1980s and 1990s, community policing is a model of policing built on increasing a sense of co-ownership of problems linked to crime and disorder within local communities. The police are no longer solely responsible for crime, and community members are no longer passive consumers; instead, members of both groups work together to identify problems and codevelop solutions. A wide range of programs and practices operate under the banner of community policing. These include community-police meetings, community police stations, local foot patrols, block watch groups, and police outreach programs.

Historically, much of policing has been reactive, relying on people to call the police to report a crime, and frontline officers spending much of their time going from call to call. In the 1990s, recognition of the limitations of this approach led a number of groups to call for a new model in which intelligence—that is, analyzed data collected from various sources—would help guide police operations. Police still respond to calls; however, under intelligence-led policing models, police also identify crime hot spots—places with

high volumes of crime and disorder—and proactively target them.

One of the newer policing strategies is evidence-based policing. Whereas other models are largely centered on offering specific solutions to frontline crime and disorder problems, evidence-based policing is a broader approach that focuses on the question of *what works* to reduce crime and increase the effectiveness and efficiency of police work. Rather than encouraging one method or route to solving crime, evidence-based policing practitioners advocate for police decision-making based on sound scientific research.

POLICY SPECIALISTS

Psychologists working as policy specialists apply their expertise in human behavior and scientific inquiry to inform and influence the development of evidence-based public policy. Psychologists possess specialized knowledge about traditional psychological concepts including, but not limited to, etiology, assessment, and treatment for mental illnesses; relevance of developmental milestones over the life span; impacts of various chemical substances introduced into the body; relationships between thoughts and actions; and many other aspects of mental health. This expertise can be shared with policy makers with the goal of

influencing program development, such as mental health parity (i.e., the requirement that health insurance carriers provide equal treatment and financial benefits for mental health and substance use disorders and medical disorders) and resource commitment in these areas.

Because of their expertise in human behavior, psychologists are also uniquely qualified to contribute to policies beyond mental health conditions or professional training and licensing issues. For example, understanding people's choices and behavior across various conditions may influence program development in areas such as promoting exercise and healthy eating, increasing recycling or *green* actions, investing or saving money, reducing criminal behavior, improving driving habits, or other social issues that interface with personal choices and the common good.

Developing effective and sustainable public policy, regardless of the issue, requires a foundation built upon evidence-based concepts, a system for evaluation, and the flexibility to adjust the policy as more data become available. Ideally, the development and implementation of a policy involve regular reevaluation and modification. Psychologists are trained in the process of investigating a body of information, reaching a conclusion, establishing an intervention or making a recommendation, and then evaluating the results and planning next steps accordingly. This process is applicable whether a psychologist is working in the research, clinical, or policy arena.

Training and Skills Needed

Traditional psychology training—including learning about human behavior and psychopathology, conducting and evaluating research, and developing advanced communication skills—serves as a strong foundation for interfacing with the public policy arena. To truly influence systemic change, psychologists must advance their knowledge at a macrolevel so as to apply these skills to complex policy and social issues. For example, in addition to applying methodological skills to critique the value of empirical research, policy specialists must be proficient in distilling complex ideas into plain language for nonpsychologists while maintaining the integrity of the information.

One must also understand policy development and implementation to be able to provide a thorough analysis for policy makers who are considering proposed policy changes or evaluating program effectiveness. Specifically, policy specialists must appreciate the transdisciplinary nature (i.e., working across disciplines to explore real-world issues and developing the accompanying skills to adapt understanding as the issues evolve) and complexity of social issues. They must demonstrate the awareness, objectivity, and flexibility necessary to collaborate with experts and thought in other fields. This includes individuals with whom they may disagree on the basis of a theoretical and/or political perspective.

Preparation for a Career in Policy

Despite the potential contributions of the field of psychology, formal training opportunities in public policy are still absent from most psychology graduate programs. As a result, students considering a career in policy may look to other disciplines providing coursework in program evaluation, policy development, the legislative process, or other courses focused on systemic analysis (e.g., economics, sociology, public health). Some policy specialists may opt for additional degree work through masters of public policy or other policy-specific programs. However, this is not a requirement for working as a policy specialist.

In the United States, most states have institutes for public policy that offer everything from open events with policy and think tank leaders to webinars, continuing education sessions, conferences, independent study coursework, internships, and fellowships. These opportunities are generally open to people from all professional backgrounds.

Professional and nonprofit organizations at both state and national levels have legislative or public affairs committees. These often serve as the drivers for prioritization and development of an organization's policy agenda. Volunteering to serve on these committees can provide one with invaluable experiences with the advocacy and the policy-making process. It can also provide one with significant networking opportunities. Some national organizations, including the American Psychological Association, offer specialized

internships and fellowships in public policy. Some local communities have created formal training programs to build capacity for current or future community leadership on local economic, educational, or social issues unique to a community.

Job Opportunities in the Policy Arena

Policy specialists are employed with policy-making bodies such as state legislatures or congress. In these settings, policy specialists may be assigned to specific committees such as Health, Human Service, or Public Safety to serve as resources for policies currently before the committee. Policy specialists may also provide similar expertise to one of the bodies (e.g., House or Senate) and/or the majority or minority political parties. In this role, one is often engaged in comprehensive analysis of current, consideration of alternative, or development of future policy proposals. Policy specialists may also work for specific lawmakers or provide consultation for a state governor's office. While in the latter position, political ideology is often aligned between the specialist and the elected official, any of these aforementioned positions may be partisan or nonpartisan.

However, policy specialists typically interface with the legislature on policy development. In this capacity, policy specialists generally meet with policy makers to provide key information and advocate for a particular stance on a policy issue. At a given time, certain approaches to policy issues may align with a particular political party. However, in this capacity, policy specialists must avoid partisanship in providing policy expertise.

Challenges and Rewards

While they vary across settings, the challenges commonly found in policy work can include the unpredictable pace and change of direction inherent in the policy-making process. This is particularly true in positions directly related to state legislatures or congress. Regardless of the setting, psychologists can experience frustration when, despite their best work or recommendations, public policies are developed inconsistently, or funded inadequately, given what is known about successful implementation and meaningful results.

However, professionals working in public policy also find great fulfillment in knowing they are using their expertise to "give psychology away." Policy specialists also enjoy using critical thinking and creativity to meet the challenge of applying scarce public resources in a manner most consistent with evidence-based data for the common good.

POST-TRAUMATIC STRESS DISORDER IN INCARCERATED OFFENDERS, TREATMENT OF

Many prisoners are in double jeopardy for post-traumatic stress disorder (PTSD). On average, their preincarceration backgrounds include more trauma than the average person experiences, and when they go to prison, new traumas await them, including overcrowded conditions, possible physical and sexual assault, and time spent in segregation. Harsh prison conditions and new traumas that occur behind bars are more difficult to cope with because of the past history of multiple traumas. Although the prison reality presents the very real danger of retraumatization, it also presents

staff an opportunity to identify traumatized prisoners and intervene to help them avoid or process potentially traumatic current events in a better way than earlier traumas were processed, resulting in a previously unattainable level of healing.

Single and Multiple Traumas

PTSD is a psychiatric condition that occurs in some (but not all) people who experience a severe trauma such as witnessing a murder, the personal experience of rape, or some other loss or painful experience that is outside the usual range of human events. The disorder consists of intrusive symptoms (e.g., flashbacks, nightmares, reliving the experience), hyperarousal symptoms (e.g., startle reaction, insomnia, hypervigilance), and constrictive symptoms (e.g., emotional numbing, isolation, fear of leaving one's cell or participating in activities or relationships reminiscent of the trauma). The intrusive and constrictive symptoms alternate over time until either they resolve, and then there is no PTSD to diagnose, or a chronic pattern of symptoms evolve, including emotional numbing, depression, constricted life, low self-esteem, insomnia, nightmares, flashbacks, reliving, and panic.

Multiple traumas have a very different effect than a single trauma, and the condition is called *complex PTSD*. The healing process that begins after a single trauma is most likely to proceed if a safe environment and sensitive help is available. On the other hand, if the trauma is repeated (e.g., repeated child abuse or domestic violence, traumas that occur in jail or prison), the repetitive traumas multiply the emotional damage and preclude real healing. A more complicated post-traumatic clinical situation results, usually with more severe and lasting symptoms and disability. In effect, just as the intensity of emotional reactions and the need to constrict affect and activities begin to lessen, a new trauma comes along and sets the whole process off again, intensifying the intrusive emotional symptoms, magnifying the arousals, and heightening the need to constrict.

Traumas in the Correctional Setting

Prison overcrowding is known to correlate with higher rates of violence, psychiatric breakdown,

and suicide. Previously traumatized prisoners are at high risk of victimization, more so with overcrowding. Rape is another significant problem. In men's prisons, it is usually prisoner-on-prisoner rape, which has more to do with male prisoners trying to establish their place in a male prison power hierarchy than with sexual desire. In women's prisons, it is more often male staff who sexually harass and abuse women prisoners. Because so many prisoners have histories of physical or sexual abuse prior to incarceration, the sexual abuse they are subjected to in prison opens old wounds. In addition, a growing number of prisoners are being placed in isolated confinement, where prisoners are confined to their cells 23 or more hours per day, and the forced idleness and isolation constitute a further form of trauma.

Often, past and current trauma affecting prisoners goes unrecognized because correctional staff are singularly focused on malingering and antisocial personality disorder. Whenever correctional professionals find themselves dismissing the concerns or complaints of a prisoner, it is an opportunity to consider the possibility that the ways in which this prisoner appears sociopathic and difficult are precisely the clues that he or she might in fact have PTSD and be expressing his or her pain in an indirect and seemingly obnoxious way—as people who have been multiply abused can do.

Treatment Considerations

People with PTSD interpret new events in relation to the past traumas, and this dampens new experiences. Meanwhile, in what may be a failed attempt to suppress or avoid the painful memories and experiences, they numb themselves and constrict their daily activities so their life lacks the vitality and spontaneity it once had. All of these circumstances need to be explored with the help of mental health clinicians. First, the prisoner who experiences trauma-related symptoms needs to feel safe, safe enough to start examining past traumas. Correctional mental health staff can help by assessing the prisoner and collaborating with custody staff to create a safe situation. After sufficient safety has been established, the second phase of treatment (remembering the trauma, mourning, and working through the traumatic experience with the help of a therapist) and the third phase

(reconnecting with other people and reestablishing a daily life) can proceed. Getting the phases out of order can cause harm. The clinician's job is to first demystify the process for the traumatized individual, counter the internalized judgments and criticism, and then set to work establishing the kind of safety that is required if a deeper exploration of the traumatic event is to occur.

The prison setting makes the aftereffects of trauma more complicated. For example, the woman who is sexually assaulted or raped remains imprisoned in the same setting where the assault or rape occurred, and often the same staff member or members who abused her remain in total control of her life. The man who has been beaten up or raped by another prisoner must continue to live among the men who witnessed his humiliation, including the perpetrator. If proper procedures are not put in place to protect the traumatized individual and to hold the perpetrator accountable, then there essentially is no safety. This is especially true when the prisoner who has been assaulted makes a complaint and insufficient or no action is taken against the assailant. Retaliation is an ever-present danger. When the trauma is related to harsh prison conditions such as isolated confinement, the clinician must also do all that is possible to improve the conditions.

The preferred treatment is some form of talking therapy—usually a combination of individual and group psychotherapy—where the individual can talk about what happened and about his or her emotional reactions. Psychotropic medications can be helpful as an adjunct to psychotherapy but alone do not constitute adequate treatment.

Staff have an important role to play during the early stages of healing from a recent trauma. By being respectful of the traumatized prisoner's need to be quiet and to be left alone at one moment and to talk at other moments, the staff member is helping the prisoner regain some control of his or her boundaries and reestablish his or her sense of safety. By being tough but fair when a prisoner needs confronting and also by knowing when and how to back off and give an ailing prisoner a little more space to regain strength and resolve, staff help the prisoner achieve a sense of the order and predictability of events. Staff should also make special efforts to be nonjudgmental when a prisoner is having a rough time emotionally following

a traumatic event. Staff should educate themselves about trauma and its emotional ramifications and share their understanding with the traumatized prisoner.

A sense of unfairness increases resentment, and resentments mount in isolated confinement and exacerbate many of the symptoms of PTSD. Fairness and evenhandedness on the part of staff can give prisoners the sense that their world is predictable, and just as they can get into trouble by committing certain acts, they can also avoid trouble by not committing those acts. The predictable nature of the prison disciplinary system, the consistency of staff, and the clarity of their choices can be reassuring and help them regain a sense of some measure of predictability and control in their lives.

Training is an important part of the picture. Staff of all disciplines should undergo training that includes not only an understanding of trauma, the traumatic backgrounds of prisoners, the signs and symptoms of PTSD, and staff interventions that are designed to prevent further trauma and aid prisoners in their healing but also an understanding of gender issues, sexual assault, violence prevention, cultural issues, and the effects of solitary confinement. The more aware and sensitive the staff, the better able they are to prevent traumas of all kinds and the better able they are to intervene effectively when traumatic incidents occur.

The effects of trauma are much more lasting than previously thought, and the presence of emotional numbing and constriction of activities creates significant disability. Prisoners who have been traumatized, especially if the traumas of prison life recall multiple traumas prior to incarceration, tend to isolate themselves, with increasing symptoms of PTSD, anxiety, depression, and lethargy. Research shows that previously traumatized prisoners who experience anxiety and depression, and fail to participate fully in rehabilitative programs, tend to make poor adjustments and resort to substance abuse after they are released from prison. On the other hand, prisoners who have experienced multiple traumas and have suffered retraumatizations in prison can do very well in prison and succeed in their postrelease adjustment when correctional staff are responsive to their special needs and when they are offered adequate treatment.

Retraumatization of prisoners who suffered multiple traumas prior to incarceration is so pervasive, and PTSD so prevalent in prison, that a comprehensive approach to prevention, detection, and treatment should be a priority in all correctional settings.

POVERTY AND CRIME

Growing economic inequality in the United States has profound implications for understanding crime, criminal justice processing, and trends in mass incarceration. Although contemporary crime rates are at levels observed during the 1960s, punishment—through the use of incarceration—remains at historic highs. As the richest nation in the world, the United States incarcerates more people than any other country. According to the National Research Council, Americans represent less than 5% of the planet's population, but U.S. inmates comprise nearly 25% of prisoners globally, and in 2014, more than 2.23 million

Americans were behind bars, representing nearly 1% of the U.S. adult population.

The risk of incarceration is not distributed uniformly across the population. Men, non-Whites, high-school dropouts, and young adults have the highest risk of incarceration. As noted by Becky Pettit and Bruce Western, on any given day, one in three African American men under age 35 years who did not complete high school is behind bars. Pettit and colleagues also note that Black men's lifetime risk of incarceration hovers close to 70% and that there are more young Black men who dropped out of high school behind bars than there are in the paid labor force.

The consequences of a criminal record are profound and cannot be ignored in assessments of increasing socioeconomic inequality. Former inmates convicted of felony offenses face barriers to employment, wage growth, housing, civic participation, and public assistance, all of which converge to impede successful reentry into society. The mark of a criminal record also deeply entrenches former inmates with nondischargeable debt for their criminal prosecutions and time served. With more than 850,000 inmates reentering society annually, successful reintegration largely depends on connecting former offenders with consistent work, permanent housing, and stable resources to limit their stress and hardship after prison.

The negative effects of incarceration also extend to the families of former offenders. Children are at an increased risk of child homelessness; internalizing and externalizing behaviors; food insecurity; and exposure to severe deprivation and material hardship, unmet health needs, and residential instability. Paternal incarceration also elevates the likelihood of severe depression among mothers, compromising the stability (including financial stability) of romantic relationships through an increased probability of divorce and relationship dissolution.

Contemporary social science evidence finds that the rise of mass incarceration is the result of poverty and inequality, not growing levels of crime. In particular, as discussed in this entry, growing inequality in punishment is a response to two social forces: (1) the social inclusion and advancement of minorities after the civil rights movement and (2) structural changes in the labor

market and criminal justice system during the late 20th century.

The Backlash Against Social Inclusion

Poverty, crime, and punishment have their antecedents in the historical context of racial relations in America as well as the structure of norms and opportunities available to disadvantaged groups. Classical criminological theory links crime and deviant behavior to economic strain and differential opportunities for success. In the late 1930s, Robert Merton argued that society determines success goals but that the structure of society facilitates or inhibits one's success in achieving these goals. Cultural norms—such as hard work and perseverance—instruct people in the actions they may legitimately use to achieve cultural goals (e.g., occupational prestige, financial success), but institutional means (i.e., legal employment and formal education) represent the distribution of opportunities for achieving culture goals by legitimate means. Anomie—a breakdown in a person's regulatory norms—ensues when there is a discordance between cultural goals and institutional means. Merton formulated a means-goals disjunction that focuses on five adaptations, one of which is the innovator adaptation, whereby an individual retains the cultural goal but rejects the institutionalized means to achieve the goal.

Consequently, the frustration and injustice associated with trying to achieve cultural goals legitimately, through cultural norms and institutional opportunities, produces strain among the severely disadvantaged. Innovators often turn to criminal activity to obtain culturally defined markers of status and success. Yet, in the late 20th century, Robert Agnew argued that unjust treatment is a distinct category of strain, representing “the failure to achieve positively valued goals” given one's inability to escape legally from painful encounters.

Mass incarceration is the latest institutional configuration to produce and maintain strain in the lives of disadvantaged men and women. Although civil rights legislation was supposed to ameliorate unequal and unjust treatment in employment, education, and voting, David Garland argued in 2001 that the civil rights movement of the 1960s produced a backlash against the social

and economic inclusion of racial minorities, ushering in conservative penal policies that would maintain dominance over people of color and the economically disadvantaged. At around the same time, Loic Wacquant showed that this conservative backlash resulted in a social policy of mass incarceration that reified and reinforced forms of discrimination and unjust treatment akin to earlier systems of racial domination and social inequality: slavery and Jim Crow. The difference between these institutional configurations of inequality, however, is that under a system of mass incarceration, the poverty and hardship experienced by potential offenders and former inmates—housing restrictions, felon disenfranchisement, broken and displaced families, employment discrimination, wage disparities, and educational inequality—can be framed under a trope of *individual responsibility* instead of overt legal discrimination. Yet, changes in the economy and criminal justice system served to bolster conservative rhetoric around individual responsibility.

Structural Changes in the Labor Market and Criminal Justice System

The decline of manufacturing during the 1970s and 1980s transformed the social ecology of cities, thereby altering the fabric of everyday life for residents in the urban core. During the mid- to late-20th century, the United States began to shift from a goods-producing, manufacturing-based economy to a service-oriented labor market. Manufacturing jobs required little skill and paid living wages. Many of these jobs were located in the inner cities of the United States. With the export of manufacturing jobs overseas, many urban residents with low levels of formal education were unprepared for a labor market that required additional skills and greater educational endowments. At the same time, the development of highways and suburbs allowed professional jobs and more economically advantaged families to move further away from the city center. As a result, concentrated poverty and economic strain in the urban core led to increasing social dislocations—crime, incarceration, teen pregnancy, and high-school dropout rates.

During the industrial decline, the labor force began to restructure itself into two distinct sectors

that comprised a segmented (or dual) labor market. The U.S. labor force became dichotomized over time into *primary* and *secondary* workers, and these two workforces differ in employer and employee expectations, pay scales, autonomy, and other attributes of jobs. The behavioral rules under which the markets operate are also different. The secondary labor market is associated with menial tasks, employment instability, low wages and no benefits, and poor and unsafe working conditions. A key feature of the secondary labor market is that there is little to no chance of advancement. The primary labor market, on the other hand, is characterized by good wages, better working conditions, and a chance for advancement. Labor market segmentation is known to produce wage differentials by race, gender, and educational attainment.

The separation of markets occurred for a number of reasons, one of which was discrimination in the behavioral requirements imposed on the workforce. Extrapolating dual labor market theory to the illicit economy of crime, Kevin Bales argued that the secondary market uniquely structured, or routed, men into criminal careers due to the very nature of the market's functioning. Economic research shows that street-level drug dealers are employed in both illicit and low-wage jobs, indicating that earnings from the illicit economy largely supplements, not supplants, secondary labor market earnings. Consequently, working in the illicit or informal economy may be an individual response to discrimination in low-wage labor markets and criminal justice surveillance. *System avoidance*—the surveillance of ex-offenders through the institutions of work, school, and banking—is a behavioral response for men who are routinely entangled in the criminal justice system and find themselves under constant threat of police apprehension, interrogation, and detention.

Economic deregulation and welfare retrenchment in the closing decades of the 20th century ensured the accelerating decline and increased hardship of the U.S. social state. Neoliberalism produced a new government of *social insecurity* that wedded supervisory *workfare* and *prisonfare*. Disciplinary workfare replaced protective welfare under the Personal Responsibility and Work Opportunity Act of 1996. Welfare was

then reconstituted as workfare, and the penal system was stripped of its rehabilitative illusions, forcing disadvantaged and marginalized populations off of public aid and holding them in confinement, especially if their alleged crime was welfare fraud.

As crime rates increased in inner cities during the 1980s, poor and blighted neighborhoods became extensively policed and surveilled, and criminal justice policies shifted to contain the threat of crime. Widespread shifts in policing, prosecution, and criminal codes changed at the local, state, and federal levels. Mandatory minimum sentences, truth-in-sentencing laws, and three-strikes legislation fueled the growth in mass incarceration, resulting in greater racial, economic, and educational inequality in incarceration, even as crime rates dropped to their 1960s' levels.

The United States governs through a fear of crime, and the consequences can be particularly devastating for marginalized and disadvantaged individuals, their families, and their communities. Poor and non-White criminal defendants disproportionately access legal aid and the services of public defenders who often seek a plea bargain with prosecutors rather than to go to trial. Upon conviction, these defendants may owe thousands of dollars in fines, fees, restitution, attorney's fees, and other court costs. This legal debt cannot be eliminated through bankruptcy, and these monetary sanctions may lead to wage and tax garnishments depending on the state. In some jurisdictions, failure to make payments toward these legal debts can trigger technical violations for probationers and parolees, resulting in their reincarceration when no new criminal offense has been committed. With a criminal conviction that limits or prevents future employment and a justice system seeking financial remuneration, former offenders are expected to reintegrate—both socially and economically—into a society that has marginalized them, in part, due to their preexisting socioeconomic status.

Conclusion

Since 1972, mass incarceration continued a steady ascent for over 35 years. Research has shown that growth in imprisonment is not due to increases in

crime or criminality but to a host of political, legal, and economic changes during the remaining decades of the 20th century. Structural changes in the labor market and criminal justice system, as well as the backlash to civil rights legislation, have contributed to growing racial and economic inequality in the United States. The social exclusion of inner-city residents and former offenders—through the neoliberal policies of economic deregulation, welfare reform, and mass punishment—creates economic and psychological strain that deeply entrenches and criminalizes poverty among the most disadvantaged members of society.

PREVALENCE ESTIMATES OF CRIME AMONG PERSONS WITH MENTAL ILLNESS

There are many myths about people with serious mental illness. The most common myth is that people with mental illness are more likely to commit criminal acts, especially those that involve life-threatening harm to other people, particularly strangers. This view is promulgated by fictional

portrayals of people with serious mental illness in films and novels as well as by sensationalized media coverage of events involving people with serious mental illness. In this entry, prevalence of criminal behavior among people with mental illness is explored, drawing on three different literatures. Each literature, at its core, explores the association between serious mental illness and offending behavior. The first literature describes the prevalence of people with serious mental illness in jails and prisons. The second, also descriptive, examines the types of crimes committed by people with mental illness. A more recent and rigorous literature explores the prevalence of crime among people with serious mental illness compared to the general population and factors that cause or mediate criminal behavior.

Prevalence of People With Mental Illness in Jail and Prison

Researchers have explored the association between serious mental illness and offending behavior in several different ways. The first, and rather simplistic, approach focuses on the prevalence of people with serious mental illness in jails and prisons. This line of research has received considerable attention because it supports the myth of the criminalization of mental illness. It has been argued that with deinstitutionalization (i.e., the systematic closure of state psychiatric institutions and a concomitant reliance on community-based treatment), people with severe mental illness were undertreated by the community-based mental health system, causing their (unmanaged) symptoms to manifest as deviance, ranging from public nuisance behaviors to violence (ranging from assault to murder). Evidence here has been used to advance the need for policies, practices, and funding to improve the community-based mental health system through interventions that target the special needs of justice-involved people with serious mental illness.

Estimates of mental illness among jail and prison populations have varied significantly, reflecting in part differences in the definition and measurement of mental illness and in part differences in sample design. When a broad definition of mental illness (e.g., treatment for a mental health problem) is used and people are asked to

self-report these problems, prevalence estimates approach in excess of 50%. That translates into approximately 1.1 million incarcerated men and women having mental health problems. The rates of mental health problems are higher among jail inmates (64%) than state inmates (56%) and federal inmates (45%). These rates fall dramatically, however, when mental illness is measured using psychometrically robust clinical diagnostic instruments administered by clinicians. Of the 2.2 million people incarcerated in U.S. jails and prisons in 2014, 14–16% are estimated to have a serious mental illness (defined to include schizophrenia, bipolar disorder, or major depression), representing approximately 330,000 people. It is typically assumed that these people are in prison because of symptoms related to their mental illness, suggesting the need for more effective mental health treatment in correctional settings and the community to prevent future criminal behavior. Although it is important to have effective treatment for all health and mental health problems inside and outside correctional settings, treatment alone does not portend the expected: lower rates of crime by people with serious mental illness.

Types of Crimes Committed by People With Mental Illness

Another related line of research has focused on the types of crimes that people with mental illness commit, with an emphasis on the relative proportions of nonviolent and violent crime. Nonviolent crime suggests that deviance is associated with social disadvantage, which may be derivative of the mental illness and the need for instrumental assistance and mental health treatment. Violent crime suggests that deviance is associated with the illness itself and the need for risk assessment interventions as well as more mental health treatment. Like the first approach, crime typologies are used to advance the need to develop and fund risk prevention interventions grounded in the management of the mental illness. Still implicit in this line of research is that mental illness is the driving direct or indirect cause behind the deviance.

The percentage distribution of crime types committed by people with mental illness depends on the correctional setting (federal prison, state

prison, local jail) and the measure of mental illness. Using a corrections-based population, nearly half of state inmates with a mental health problem were convicted of a violent offense (defined as homicide, sexual assault, robbery, or assault), compared to roughly one quarter of jail inmates with a mental health problem (comparable to the percentage distribution of crimes for inmates without a mental health problem in each setting). One in five state inmates with a mental health problem had either a property or drug offense as their most serious offense, followed by approximately 1 in 10 having a public-order offense. The most common type of offense by state inmates with a mental health problem was robbery, followed by drug trafficking and homicide. Of jail inmates with a mental health problem, nearly one in four had a property, drug, or public-order offense as their most serious offense. Assault was the most common offense for jail inmates with a mental health problem, followed by drug possession and trafficking. These percentage distributions suggest that the crime profiles of prison or jail inmates with mental health problems are similar to their counterparts without mental health problems. Jail inmates with mental health problems, however, are slightly less likely to have public-order offenses and drug offenses as their most serious offenses but are slightly more likely to have property offenses.

Instead of looking at the crimes committed by those who were arrested, researchers can examine the crimes committed by those who were receiving mental health services. In a study of 13,816 individuals receiving services from the Massachusetts Department of Mental Health, Bill Fisher and colleagues found that of those who had been arrested over a 10-year period, the most frequent offense leading to an arrest was crimes against public order (e.g., disorderly person, disturbing the peace, false alarm, trespassing), representing 16% of the population. The next most common offenses were serious violence against persons (14%) and property offenses (10%).

Prevalence of Crimes Committed by People With Mental Illness

Research since the mid-2000s has focused attention on the relative rates of crime between people with

mental illness and the general population (without serious mental illness). This research draws into question the assumption that serious mental illness causes crime. Instead of assuming that serious mental illness causes deviance, other risk factors (e.g., substance abuse, environment, criminal thinking, joblessness) are explored. These are risk factors that are common to people who engage in crime, independent of their mental health status.

The 2006 study by Fisher and colleagues was the first of its kind to examine the extent to which people with serious mental illness (defined as having schizophrenia, bipolar or major affective disorder, significant functional impairment, or an intensive service use history) were arrested. They found that approximately 28% of the cohort had experienced at least one arrest over a 10-year period, with a modal number of two arrests and a range from 0 to 71 arrests. Arrests were concentrated in a small number of the cohort; nearly 17% of all arrests were associated with 190 people, and 13 people experienced arraignments in each of the 10 years. Arrests were more likely among men, non-Whites, and those aged 18–25 years. This research confirms patterns documented in the broader criminological literature regarding the concentration of criminal behavior in a small number of people and the sociodemographic characteristics that predict criminal behavior.

Building on this research, Seena Fazel and colleagues explored the connection between serious mental illness and violent crime by comparing rates of violent crime (defined as assaults or other violent crimes) between people with and without serious mental illness. In separate studies, people with schizophrenia and bipolar disorder were modestly more likely to commit a violent offense compared to people in the general population if substance abuse disorder was not present. For those with schizophrenia or bipolar disorder and a substance abuse disorder, violent crime was 5–6 times more likely among those with dual disorders compared to people without a mental disorder. When compared to sibling controls without mental illness, the violent risk differential reduced significantly, suggesting that genetics or early childhood history played a mediating role. This study confirms findings from other similar studies. When factors that more fully characterize the individual and community are used as controls, the connection between serious mental illness and

violence diminishes and, in some cases, disappears altogether. From this research, the important message is that people with serious mental illness are similar to people without mental illness when it comes to the dynamic that motivates violent behavior. There are many risk factors, such as substance use, family history, environment, and socioeconomic factors (e.g., poverty, joblessness, homelessness) that directly and indirectly interact to predict violent behavior.

Normalization of Offenders With Serious Mental Illness

Three conclusions can be drawn from these literatures. People with serious mental illness

- (1) are overrepresented in incarcerated settings,
- (2) have offense patterns similar to those of offenders without mental illness (i.e., small number of people committing a disproportionate number of offenses and arrested primarily for nonviolent offenses but incarcerated in state prisons primarily for violent offenses), and
- (3) have personal characteristics and social circumstances that are known risk factors for criminal behavior.

Taken together, this research suggests that offenders with serious mental illness are more similar to their counterparts without mental illness than they are dissimilar. That is, serious mental illness, itself, does not, in the majority of cases, create a different group of offenders.

There is a growing body of research that challenges the myth that people with serious mental illness are tangled in the criminal justice system primarily because of symptoms of untreated mental illness. Consensus is building around compelling evidence that shows only a small proportion of offenders with serious mental illness (estimated at about 10%) come into contact with the criminal justice system as a direct result of symptoms related to their mental illness. The larger proportion (about 90%) of these offenders have a serious mental illness, but the illness is not the direct cause of the contact. By focusing attention on these other factors, such as history of antisocial behavior, antisocial personality, criminal thinking,

substance abuse, joblessness, homelessness, and neighborhood dynamics, offenders with mental illness are reintegrated into the normal group of offenders and body of literature on desistance that emphasizes changing patterns of thinking, association, coping, and social exclusion. Mental health treatment is necessary for all people with serious mental illness, but it alone will not prevent criminal behavior for the majority of those who face the same risk factors as people without mental illness.

PREVALENCE ESTIMATES OF MENTAL ILLNESS AMONG OFFENDERS

Prevalence estimates examine the number of people in a population who have a specific disorder or problem. Since the criminal justice system is made up of several separate but interrelated components (e.g., jails, probation), the prevalence of people

with mental illness is determined by the number of people in specific components of the criminal justice system who have a mental illness. To understand the scope of criminal justice involvement among people with mental illness and to ensure that adequate resources are available for their care and treatment, criminal justice and mental health authorities need to obtain accurate prevalence estimates of mental illness. This entry discusses how many people with mental illness are involved in the criminal justice system and how these levels of involvement vary across different components of the justice system.

An Overview of Prevalence Estimates

Research on the prevalence of people with mental illness in the criminal justice system shows that large numbers of these individuals come into contact with the criminal justice system each year. However, prevalence estimates vary widely, with rates ranging from 6% to 64%. A number of explanations for this wide variation in prevalence estimates relate to how the research was conducted. For example, differences in research methodologies and the definition of mental illness applied impact prevalence estimates. In addition, the criminal justice system is made up of several interrelated components with varying levels of contact with people. Consequently, some variation in prevalence estimates is expected across the key components of the criminal justice system. For example, police officers have contact with the broadest range of citizens, and police and probation departments both have contact with more citizens each year than jails or prisons. Therefore, existing prevalence estimates are best understood when evaluated within the context of the criminal justice setting from which they were generated.

Incarceration: Prisons and Jails

The number of studies that examine the prevalence of people with mental illness in jails and prisons grows each year. Estimates of the prevalence of mental illness in jails and prisons vary from 6% to 64%, due to differences in how broadly or narrowly mental illness is defined in each study and the research methods used to identify people with mental illness. Linda Teplin and

her research associates conducted one of the most widely cited studies of the prevalence of mental illness in incarcerated populations in Chicago, IL, jails in the 1980s. Teplin's research group used structured diagnostic interviews to determine how many people in a random sample of individuals booked in the county jail had major depressive disorder, bipolar disorder, or schizophrenia. This study found that 6% of men and 15% of women had a mental illness at the time they were interviewed.

Henry Steadman and colleagues conducted a study between 2002 and 2006 of the prevalence of mental illness in jails, the results of which were published in a widely cited article in 2009. This study used systematic sampling techniques to select samples of recently admitted inmates in five different jails of varying sizes in Maryland and New York. Similar to Teplin's research, Steadman's team also used a structured diagnostic interview to assess how many people in their sample had at least one of the following mental health diagnoses at the time of the interview: major depressive disorder, depressive disorder not otherwise specified, bipolar disorder, or schizophrenia spectrum disorders. This research found that 15% of men and 31% of women had at least one of these prespecified diagnoses.

Due to the use of rigorous research methods and widely agreed upon definitions of mental illness, Teplin's and Steadman's studies are considered by many to be the most empirically defensible estimates of the prevalence of mental illness among incarcerated adults in the criminal justice system. However, there are other studies of the prevalence of mental illness in jail and prison populations that require consideration.

In a 1999 publication for the Bureau of Justice Statistics, for example, Paula Ditton presents one of the most comprehensive assessments of the prevalence of mental illness in the criminal justice system. This research assessed the prevalence in local jails, state and federal prisons, parole, and probation. The prevalence estimates in this report are drawn from data collected from surveys administered to jail and prison inmates in 1996 and 1997. These surveys used random sampling methods to recruit nationally representative samples of offenders incarcerated in jails and

state and federal prisons. Survey participants were identified as having a mental illness if they self-reported a current mental or emotional condition or self-reported an overnight stay in a mental health inpatient treatment program at some point in the past. According to this study, 16% of inmates in jails and state prisons and 7% of inmates in federal prison had a mental illness. The definition of mental illness used in this study has limited utility in terms of resource allocation because it does not correspond to diagnoses that are typically used to identify people with mental illness in treatment settings. Therefore, questions remain about the severity and types of mental health illnesses present among individuals in these samples. Despite this limitation, the use of a nationally representative sample allowed the researchers to use the prevalence estimates they developed to estimate that 283,300 people in jails and prisons in the United States had a mental illness as of June 30, 1998.

In 2006, Lauren James and Doris Glaze published the other prevalence estimate that is widely cited in the literature. Similar to Ditton's research, this study used data from surveys of a nationally representative sample of inmates incarcerated in jails and state prisons in 2002 and 2004. However, in this study, the survey questions were drawn from a structured diagnostic interview, similar to the ones used by Teplin and Steadman. The diagnostic questions used in this survey were designed to identify people who were experiencing mental health symptoms associated with mental illnesses, such as major depression, manic episodes, and psychotic disorders. The goal of this survey was to identify people experiencing symptom distress, not individuals with specific mental illnesses. Therefore, the research did not include any of the additional diagnostic steps related to assessing the severity or duration of the symptoms and did not exclude people who were experiencing symptoms for reasons other than mental illness (e.g., medical illnesses or substance use problems). This research found that 64% of jail inmates and 56% of prison inmates reported experiencing emotional distress at the time of the interview. Since this research is unable to determine how many of these individuals were experiencing emotional distress due to a diagnosable

mental illness, the results should be interpreted with caution when discussing the prevalence of mental illness in the criminal justice system.

Community Supervision

Although the vast majority of people under the supervision of the criminal justice system are on probation, parole, or some other form of postrelease community control, only a few studies have estimated the prevalence of mental illness in these populations. Existing research found prevalence rates varying between 16% and 27%. One of the first studies to estimate the prevalence of mental illness among probationers was published by Ditton in 1999. This research used data from a 1995 survey of a nationally representative sample of probationers. In this study, a person was identified as having mental illness if they reported either a current mental condition or previous overnight stay in a mental hospital. This research found that 16% of probationers had a mental illness.

Another frequently cited prevalence estimate of mental illness among probationers comes from research conducted by John Crilly and colleagues. This research used data from the 2001 National Household Survey on Drug Abuse to estimate how many people who self-reported symptoms of mental illness had been on probation in the last year. This research found that 27% of people in their sample reported symptoms of mental illness and a period of probation in the last year.

Due to the paucity of research on the prevalence of mental illness among people under community supervision, these two studies provide valuable information. However, each study used a definition of mental illness that was much broader than the diagnostic categories typically used to identify mental illness and allocate resources. Additionally, the utility of the prevalence estimates generated by Crilly and colleagues' research is limited by the fact that the sample was drawn from a population of people living in the community rather than a population of people on probation. Therefore, the prevalence estimates generated from this research represent the percentage of people in the general population with a history of probation who have a mental health problem, not the percentage of people on probation with a mental illness. Although this

research suggests that a substantial portion of probationers could have a mental illness, more research needs to be conducted in probation populations to determine the prevalence of mental illness.

Police–Citizen Interactions

Several studies have examined the prevalence of mental illness in police–citizen interactions. Since most contacts with police are brief, prevalence studies in this setting require researchers to use observational methods. Teplin and colleagues conducted a seminal study of the prevalence of mental illness in police–citizen interactions in Chicago in the 1980s. In this study, staff used a structured clinical checklist that enabled researchers to observe police interactions with citizens and make an assessment of the presence of individuals presenting with behaviors associated with diagnosable mental disorders. In this study, the researcher's assessment of the presence of mental illness was made independently of the police officer's assessment. Results indicated that 6% of police–citizen encounters involved a person with a mental illness.

A second study, conducted by Robin Shepard Engel and Eric Silver, examined police–citizen interactions involving people with mental illness. Engel and Silver used data collected from two earlier research studies (i.e., the Project on Policing Neighborhoods and the Police Services Study) to assess the prevalence of mental illness in police–citizen interactions. Similar to Teplin's research, both of these studies used trained research staff to observe police officers' interactions with citizens. However, unlike Teplin's study, the observational method used in these studies was designed to identify situations where police officers believed the citizen was mentally ill. This research found that 3.6% of police contacts in the Project on Policing Neighborhoods and 2.7% of contacts in the Police Services Study involved a suspect with a mental illness.

Future Directions

Prevalence research shows that the involvement of people with mental illness in the criminal justice system is pervasive and disproportionately high. This is evidenced by the fact that even the most conservative prevalence estimates find rates of

involvement of people with mental illness in the criminal justice system that are much higher than those in community settings. Although there is significant variation in prevalence estimates, it is clear that there are large numbers of people with mental illness within and across criminal justice settings. Therefore, each segment of the criminal justice system needs to generate accurate prevalence estimates to ensure that adequate resources are available to see to the care and treatment of these individuals.

preventing future crime by those who have previously engaged in delinquency activities. Most crime prevention programs are operated outside the formal criminal justice or juvenile justice system. This entry discusses both crime prevention and correctional interventions, research on their effectiveness, and conclusions scholars have drawn regarding prevention versus intervention.

Crime Prevention

Crime prevention may be categorized into three systems. First, *developmental crime prevention programs* target individual risk and protective factors that are known causes of delinquency. One type of crime prevention is early childhood programs such as preschool education and home visits, which attempted to improve the child's education and parenting. Other programs focused on providing attention, activities, and mentoring for youths. Second, *community prevention programs* target residential communities by changing the social conditions and institutions. Community prevention programs focus on improving opportunities in disadvantaged neighborhoods or on making the community safer through such efforts as neighborhood watch. Lastly, *situational prevention programs* focus on reducing the opportunities for delinquency and increasing its risk and difficulty. Efforts can include improved street lighting to hot spots and community policing.

The current era of crime prevention evaluation may be traced back to 1997 when the U.S. Congress commissioned Lawrence Sherman and his colleagues to examine more than 500 programs to determine their effectiveness. This report, *Preventing Crime: What Works, What Doesn't, What's Promising*, used a scientific methods scale to rate US\$4 billion worth of federally funded anti-crime programs. The results classified programs into three categories: what works, what is promising, and what does not work in crime prevention. The following programs were found to be effective: preschool and weekly home visits by teachers for children under 5 years of age, family therapy and parent training for at-risk youth, social competency skills training programs, and nuisance abatement programs. Programs that were not effective include gun buyback programs, drug abuse resistance education programs, neighborhood watch programs organized by police, and storefront

PREVENTION VERSUS INTERVENTION

Crime prevention refers to efforts to prevent delinquency from occurring before a crime has ever taken place, whereas intervention is focused on

police offices. Programs that were considered to be promising include gang monitoring by community workers, mentoring programs, and battered women's shelters.

Correctional Intervention

There has been considerable debate about the definition of crime prevention. Are only efforts that prevent an initial instance of crime considered to be crime prevention or are police and correctional efforts at crime reduction also considered to be prevention? As both police and correctional efforts seek to prevent future crime, some people include such efforts in their definition of crime prevention. Others, however, see criminal justice system efforts at crime prevention, especially correctional interventions, as crime control efforts that aim to prevent further offending. Correctional treatment is an intervention that seeks to prevent future reoffending. One of the most critical issues concerning criminal justice interventions is the effectiveness issue: Do the interventions have any impact on the criminal or delinquent behavior of their charges?

Research

Research indicates that two thirds of prisoners released from prison are arrested within 3 years after release from prison and about 45% return to prison. The numbers are lower for juvenile delinquents with about 55% being rearrested and 12–25% being reincarcerated. Accordingly, recidivism (whether measured by rearrest, reconviction, or return to incarceration) is a critical issue.

While much of the program effectiveness research has focused on specific programs, some researchers have tried to summarize individual program research into a global conclusion on effectiveness. Most of these studies have used the technique of meta-analysis. With this technique, researchers reanalyze individual studies and arrive at a summary statistic of effectiveness for each individual study that can then be compared to the summary statistics from the other studies.

In 2009, Mark Lipsey conducted a meta-analysis of 548 study samples and found that there were many instances of programs that had positive effects. The most effective treatment types had an impact on recidivism that was equivalent to

reducing a control group baseline recidivism rate of 50% to 37–39%. If the recidivism rate for these juveniles would have been 50% without treatment, the most effective programs reduced it by approximately 25%. Successful interventions included counseling, multiple services, skill building, and restorative programs. More specifically, cognitive behavioral therapy, mentoring, and group counseling programs were found to be effective intervention strategies. Deterrence and discipline programs actually made recidivism worse.

The research into effective programs has culminated into three principles: the risk principle, the need principle, and the responsivity principle. The risk principle argues for matching program intensity to offender risk level. The need principle has found that targeting criminogenic needs such as the need for drug treatment relates to successful outcomes. Targeting noncriminogenic needs such as self-esteem, on the other hand, does not produce lower recidivism. The responsivity principle argues that the style and mode of treatment needs to be matched to each offender's learning style.

The Washington State Institute for Public Policy has been summarizing the research on effective and ineffective and cost-effective versus non-cost-effective programs since the 1990s. As of 2016, the institute listed 30 interventions for adults that produce cost benefits of over US\$8,000 per offender and eight programs that produce benefits from over US\$2,500 to just under US\$8,000. Some of the notable programs that are effective for adult offenders are employment and job training assistance during incarceration; therapeutic communities; risk, need, and responsivity supervision; cognitive behavioral treatment (for high- and moderate-risk offenders); and drug courts and mental health courts.

For juveniles, the institute listed 25 cost-effective programs and four ineffective programs. Effective programs include family-based therapy, functional family therapy (both in institutions and for youth on probation), cognitive behavioral therapy, aggression replacement training, therapeutic communities, multisystemic therapy, and drug courts. Two notable ineffective approaches for juveniles are intensive probation supervision and confrontational programs. To give specifics, as of 2016, the inventory of juvenile justice programs shows that for functional family therapy

there is a 99% chance that benefits will exceed costs and the estimated benefit per offender is US\$28,723. For cognitive behavioral therapy, there is a 94% chance of benefits exceeding costs, and the estimated benefit is US\$10,742. For Scared Straight, a confrontational program, there is only a 4% chance of benefits exceeding costs, and the estimated benefit is actually a loss of US\$8,802. In the middle are drug courts with a 57% chance of benefits exceeding costs and an estimated benefit of US\$1,715.

The argument can be made that effective juvenile interventions are even more effective than what the Washington State Institute for Public Policy listed. The institute computes costs compared to a youth who would commit a delinquent act and be processed as a juvenile offender. If the treatment prevents such juvenile offending (delinquent behavior) and also prevents criminal offending later in life, then the intervention is even more effective. It serves as a means of preventing adult criminal behavior in future years.

A point worth emphasizing is that several interventions that would appear to be effective are not effective. Specifically, both Scared Straight-type programs and boot camp prisons have not been effective in reducing recidivism. Scared Straight and other confrontational programs involve bringing juveniles to an adult prison, giving the juveniles a tour or firsthand look at prison cells, and then having a group of hardened criminals lecture the youths about the horrors of prison life such as the possibility of a youth being sexually assaulted (*raped*) should he or she become a prisoner. Boot camp prisons involve 90 days of imprisonment with a heavy emphasis on physical training—such as 5-mile runs, exercises, push-ups, pull-ups—and verbal abuse from a drill instructor. These efforts appeal to common sense or the experiences of many law-abiding citizens.

However, the research on Scared Straight, boot camp prisons, and even the death penalty simply does not provide evidence of effectiveness. There are several explanations for this finding. First, law-abiding individuals who jump to the inference that programs such as these seem promising are individuals who most likely are well attached to others and committed to school, a job or career, and a family. So those who went through a military boot camp, for example, were already

well socialized and controlled (to slip into sociological jargon). A military boot camp has a lot to build on, whereas a prison boot camp has to work on youth who frequently have a problematic family background, have a history of problems in school, have grown up in a poor neighborhood with reduced chances for employment, and have a number of delinquent peers.

Another issue that merits discussion is that even successful correctional interventions do not change everyone. As noted, recidivism might go down from 50% to almost 35% in a sample of several hundred offenders. So often a percentage, perhaps even an alarming percentage of offenders, commits new crimes despite the best efforts of even a well-thought-out and well-implemented intervention. So personal motivation and dedication are an important part of correctional interventions. Another reason why some offenders may not be impacted by any given correctional intervention is treatment integrity. This refers to the problem that for an intervention to be effective, the program must truly implement the program as intended. If the program is not in fact carried out as intended, there is no reason to expect a successful result.

Program Effectiveness

The research indicates several conclusions about effective interventions. First, a variety of evidence-based interventions have been shown to reduce crime and delinquency. Second, these effective interventions also produce cost-benefit savings. This is an important selling point for both legislators and taxpayers. Even some legislators and taxpayers who might support tough measures against convicted criminals might be persuaded to support less stringent measures if they reduce recidivism and produce cost savings. Third, a number of interventions that have intuitive and popular support are not effective. As noted earlier, efforts such as Scared Straight, boot camp prisons, and even the death penalty do not have evidence of effectiveness or cost savings. Fourth, it can be argued that effective juvenile interventions merit even greater attention since they offer the potential benefit of preventing criminal activity when the youth becomes an adult. Finally, the search for effective interventions is far from over. While there

is clear evidence of effective and cost-effective interventions, there is still considerable room for the search for even more effective and more cost-effective programming.

Prevention or Intervention

Prevention and intervention are usually seen as opposite ends of the spectrum, and criminal justice and correctional agencies struggle to be effective with both programs. Prevention programs are a local-level operation and facilitated by community organizations. Many prevention programs focus on community-level programs such as neighborhood watches or early intervention for at-risk youth. The target population for these programs are youth who are living in at-risk neighborhoods or those whose families have characteristics conducive to criminality. While these programs are community operated, states do provide some funding through prevention grants. It may be through these funding opportunities that states require outcomes through reduction in risk factors.

In contrast, intervention programs are reserved for those individuals who have committed an offense and are involved in the criminal justice system. Given the vast number of offenders, agencies are now using the scientific principles of risk, need, and responsivity to identify the higher risk offenders and provide sufficient dosage of quality treatment. Specifically, agencies have lower rates of recidivism when the crime-producing needs of higher risk offenders are given cognitive behavioral programming. In addition, intervention agencies may be state operated or community operated, but both have the main goal to prevent future criminality.

Trying to prevent crime, whether initially or future occurrences, is a difficult task for many states. Rather than seeing prevention and intervention as polar opposites, states could operate on a continuum and provide services to address risk factors at each step in the process. Furthermore, large-scale research studies have identified promising and effective programs for both prevention and intervention. Agencies could require programs to adopt these services and monitor the implementation and fidelity of the services.

PREVENTIVE DETENTION LEGISLATION

Preventive detention legislation enables an individual to be incapacitated to prevent harm from occurring either before they cause harm or to stop them causing more harm. Preventive detention legislation stands in contrast to the traditional retrospective orientation of the criminal justice system, whereby the state responds to harm that

has occurred, such as by prosecuting and punishing criminal acts. There are many types of preventive detention legislation, including those

- prescribing limited or indefinite detention;
- prescribing detention in a prison or other institutional setting, such as a mental health facility;
- empowering a judge or member of the executive to order detention; and
- directed at persons who have been charged with a criminal offense, convicted of a criminal offense, or neither.

A common feature of contemporary preventive detention legislation is a reliance upon assessments of risk and dangerousness (i.e., what an individual might do) rather than past acts (i.e., what an individual has done), even if the latter forms part of the prediction of future harm. It is for this reason that preventive detention legislation is controversial, and debate exists as to its place in a justice system. This entry discusses the different types of preventive detention legislation and explores key policy challenges and legal concerns they raise.

Types of Preventive Detention Legislation

There are a number of different preventive detention legislative regimes, with some connected to, and many separate from, the criminal justice system.

Civil Commitment

Civil commitment laws enable the preventive detention of a person who has severe substance dependence, mental illness, an infectious disease, or other legislative precondition. This type of preventive detention is protective and therapeutic, designed to protect the public and the individual subject to an order, and is ordered following civil proceedings that are separate from the criminal justice process. For example, in New York, civil commitment laws enabling the preventive detention of persons with mental illness require clear and convincing evidence that the person has a mental illness (as defined in the relevant legislation), needs psychiatric care and treatment, and is a risk of serious harm to themselves or others.

Civil commitment may also be used as a diversionary pathway out of the criminal justice system, for example, for persons with mental illness who have committed a minor offense and who are in need of care and treatment.

Immigration Detention

In a number of countries, including Australia, the United Kingdom, and the United States, a person may be administratively detained when a decision is being made about whether to admit or remove the person. Foreign national prisoners, for example, can also be detained at the completion of their sentence pending deportation.

Preventive Detention Absent Charge: Criminal Justice and Military Contexts

There are also forms of preventive detention legislation that do not require a precondition, such as mental illness. An individual need not even be charged with a criminal offense. In the United Kingdom, for example, a terrorist suspect can be detained for up to 14 days by the police without charge to enable the police to obtain, preserve, or examine evidence for use in criminal proceedings. In Australia, anti-terrorism preventive detention orders can be made against a person who has not been arrested or charged. Police may detain a person for up to 14 days to prevent a terrorist attack or to preserve evidence following an attack.

Preventive detention without charge or trial also occurs in a military context. Since 2001, the United States has detained noncitizens believed to be part of Al-Qaeda or engaged in terrorism-related activity without trial in Guantanamo Bay, Cuba. Wartime internment, used during both world wars by many nations, and in Northern Ireland into the 1970s, is another example of this form of preventive detention against enemies or enemy aliens regarded as a threat to the state.

Pretrial Preventive Detention

Pretrial preventive detention occurs where an individual who has been charged with a criminal offense is remanded in custody until they stand trial, on the basis of their dangerousness or risk. This type of preventive detention was found to be

constitutional in the United States in the 1987 case *United States v. Salerno*, which related to the provisions of the federal Bail Reform Act of 1984. The Bail Reform Act requires a federal court to order the detention of persons charged with certain serious felonies if the court finds that the safety of any person or the community cannot be ensured by release conditions.

According to the *World Pre-trial/Remand Imprisonment List*, in November 2016, the recorded number of persons in pretrial or remand detention (defined as detention prior to sentence) is more than 2.5 million, with a further 500,000 estimated in countries without data. The study also reported that there were approximately 467,000 people in pretrial detention/remand imprisonment in the United States.

Preventive Detention of Accused Persons Found Unfit to Stand Trial

If a person is mentally unfit to stand trial, that is, unable to comprehend the proceedings and communicate at the time of a criminal trial, he or she cannot be tried without unfairness and injustice. Preventive detention regimes exist to allow for persons found unfit to stand trial to be held, for purposes of treatment, in prison or another institutional setting such as a mental health facility. Some jurisdictions, such as New Zealand, provide for limited detention. For example, a person found unfit to stand trial in relation to an offense carrying a sentence of life imprisonment can be preventively detained for a maximum of 10 years. In the Australian state of Western Australia, by comparison, a person found unfit to stand trial may be indefinitely detained, without trial, for any offense that has a penalty of imprisonment.

Preventive Detention at Sentence

Preventive detention can also be imposed at the time of sentence, through indefinite or indeterminate sentencing regimes. These types of regimes allow a judge to impose a nominal or tariff sentence, at the completion of which the individual will be preventively detained if and until a parole board determines the person can be released as they no longer pose a threat to the community. For example, the United Kingdom introduced a

regime of indeterminate sentences, imprisonment for public protection, which commenced operation in 2005. This regime was directed at serious sexual and violent offenders who a court was satisfied posed a significant risk to the public of serious harm through further offending. After serving a tariff sentence, an individual would be preventively detained until the parole board was satisfied he or she posed no risk to the public. In 2010, the Chief Inspector of Probation and the Chief Inspector of Prisons jointly reported that there were 70 people being sentenced to imprisonment for public protection each month. The regime was abolished in 2012. It was replaced with an extended determinate sentence framework, where the sentence can be extended by a court but not longer than the maximum penalty for the offense.

Postsentence Preventive Detention

In contrast to measures imposed at sentence, postsentence regimes enable preventive detention to be imposed at the end of an offender's sentence of imprisonment. This type of preventive detention is ordered not at the time of sentence but proximate to its expiration. Following Washington and Minnesota in the early 1990s, sexual predator laws enabling the preventive detention of sexually violent offenders with mental or personality disorders at the end of their sentence have been introduced in 19 states and at the federal level in the United States. In the 1997 case *Kansas v. Hendricks*, the United States Supreme Court held that the government must prove that the individual has a condition that makes controlling the dangerous behavior difficult or impossible. In 2006, there were reported to be 4,534 people detained under sexually violent predator laws in the United States.

The United States is not the only country to have adopted this kind of preventive detention. Since the 2000s, many Australian jurisdictions have introduced legislation permitting the postsentence preventive detention of serious sex offenders, high-risk violent offenders, and terrorist offenders. These orders enable an offender to be detained in custody, indefinitely, at the completion of their sentence when it is shown that he or she poses a serious danger to the community if released.

Dangerousness and Risk in Preventive Detention Legislation

Preventive detention legislation raises significant policy, legal, and human rights concerns. These include concerns related to constitutional validity, principles of procedural fairness, the presumption of innocence, proportionality and finality in sentencing, principles against retrospectivity and double punishment, and the right to security and liberty of the person.

Pretrial and postsentence preventive detention orders straddle the civil-criminal divide. For example, although postsentence preventive detention orders are connected to a criminal process, in that an individual may be detained upon the completion of a term of imprisonment, they are imposed consequent to civil proceedings for the purpose of public protection—not punishment—and at a point in time after that which is traditionally accepted in the criminal justice system. An individual may be detained without the enhanced procedural and evidentiary safeguards that attach to the criminal justice system.

A key issue for preventive detention regimes is the accuracy and reliability of risk assessments. A preventive detention regime that is not founded on accurate and reliable risk assessments will be error prone, thus undermining its ability to protect the public by targeting those individuals likely to cause harm or reoffend. Preventive detention regimes have not always contained a predictive element. In the 19th century, early laws enabling indefinite detention at sentence were concerned with incapacitating habitual offenders, with their danger viewed as emanating from their recurrent breach of the law, until they were reformed. It was not until the 1970s, with the growth of actuarialism and risk in the prediction of dangerousness, that preventive detention regimes began to be concerned with what an offender might do. The United Kingdom's imprisonment for public protection regime demonstrates the policy challenges preventive detention regimes pose. Prior to its repeal, the regime was criticized for the difficulties it created for prisoners to prove they no longer posed a risk and for drastically increasing the prison population and rates of mental illness among prisoners.

Postsentence preventive detention is arguably geared toward achieving the most accurate

prediction of dangerousness and future offending. Rather than attempting to assess risk at the time of sentence, postsentence regimes enable the making of an order proximate to the expiration of the offender's sentence. The goal is to facilitate the most reliable assessment of risk and increase the likelihood that it will apply only to those who pose a high risk to the community prior to release. However, Patrick Keyzer and Bernadette McSherry highlight that this form of preventive detention can be counterproductive. Their interviews with professionals working in the area unveiled concerns about the increased risks created by postsentence preventive detention regimes. One main concern is that they only target known offenders and do not reduce recidivism. The community, relying on the regime, falsely believes they are protected from sex offenders. A second is that the regime increases offenders' anger and dissatisfaction.

Preventive detention legislation is not a new legal development, although it is an increasingly prominent feature of the legal landscapes of Western nations after the terrorist attacks of September 11, 2001. The growing emphasis on risk also has implications for how those subject to the law are conceived. Eric Janus argues that risk is becoming the new marker of otherness, replacing race, gender, disability, and sexual orientation. He argues that the anti-terror and sex offender legislative schemes in the United States are creating an alternative system of justice without, or with a diluted version of, the normal civil liberties protections afforded.

PRISON ABOLITION

Prison abolition is an organizational framework and political analysis aimed at eliminating the use of imprisonment, policing, and techniques of surveillance as a means for solving social, economic, and political problems. While some may dismiss the notion of a world without prisons as a utopian and even dangerous vision, abolitionists insist through rigorous historical scholarship and political analysis that the prison itself exists only by way of its historical contingencies and that the abolition of slavery was once subjected to the same dismissals.

Guided by an intent to reorient discussions of crime and crime control outside the dominant paradigms of criminal justice policy and discourse, prison abolition aims to demystify and subvert the underlying assumptions and myths that produce and sustain both criminalization and the *common sense* of imprisonment as a response to it. Composed of a collection of diverse scholarly and political orientations, abolitionist thought liaises around a response to the failure of the state to provide effectively for a more stable, safer, and equal society through repressive and retributive measures. Fundamental to abolitionist positions is a broad attentiveness to and comprehensive aspiration toward the elimination of state violence exacted by and maintained through systems and institutions of penal control.

Abolitionists’ work examines the inequities maintained through violence, control, and imprisonment to expand a theoretical and political position that challenges the racial capitalist state more broadly, in particular its use of police and carceral

power as primary recourses for resolving crises arising out of historically embedded and deeply rooted social issues.

Origins of Abolition

Prison abolition is an inclusive and interdisciplinary perspective and protracted process, which cannot be ascribed to a single historical episode. Importantly, however, there are moments in abolition’s genealogy that may be understood to serve as points of emphasis and expansion. First, prison abolition necessarily and intentionally invokes the abolition of slavery. More than just a rhetorical provocation, abolitionists insist on the historical continuity of the term in order to gesture to the intimacies between different racial capitalist regimes across time. Prison abolitionists point out that 19th-century reformers often criticized slavery abolitionists for their uncompromising vision and instead pushed for incremental pivots away from slavery. In this same way, prison abolitionist thought argues that history will also prove that the practice of caging people, almost all of them poor, was a technology of the capitalist state that needed abolition, not reformation.

Second, abolition entered into present vocabulary through activist scholarship in the 1970s that centered on criminalization, policing, and imprisonment in its analysis of broader forms of social repression carried out by racial capitalist states. Publications such as *The Struggle for Justice* by the American Friends Service Committee, Thomas Mathiesen’s *The Politics of Abolition*, Tony Platt and colleagues’ *The Iron Fist and the Velvet Glove*, George Jackson’s *Soledad Brother*, and Stuart Hall and colleagues’ *Policing the Crisis: Mugging, the State, and Law and Order* set the conditions of possibility and terms of analysis for modern-day abolitionist scholarship and activism to emerge. These works were incisive and prescient, as Western practices of imprisonment would grow exponentially in the decades to follow.

Abolition’s third historical node, then, emerged as a radical intervention into the changing and expanded nature of the neoliberal carceral state at the close of the 20th century. As the United States became the global leader in imprisonment, radical intellectuals and social movement organizations

offered an expansive abolitionist political framework that situated a critique of the penal system within a broader analysis of the racial capitalist state under neoliberalism. The term *prison industrial complex*, first circulated by authors such as Mike Davis, Angela Y. Davis, and Eric Schlosser, became a central analytic for abolitionist organizing and research in order to speak to the state's use of surveillance, policing, and imprisonment to solve economic, political, and social problems.

Crime, Criminalization, and Punishment

The carceral project has become deeply embedded within all aspects of social life. As such, abolition offers materialist and ideological interventions that target the carceral project at various scales of its expression, from the structural conditions of its possibility to the quotidian ways humans manage conflict and violence within its context. Still, there are general themes around which abolitionist thought unites. Abolitionism foremost contends that alternative responses to interpersonal and state violence that function wholly apart from the criminal justice system are possible. To achieve this end, however, it is essential to map out the unifying links between interpersonal, state, and international violence so as to portray the ways in which violence manifests itself at the intersection of these points within a structural context. This strategy allows for the formation of networks of solidarity across diverse groups and individuals suffering under carceral practices.

Articulated through an individualizing discourse, carceral logics and practices of control, containment, and punishment both nourish and sustain oppressive relations within society. Western philosophies of justice articulate criminality as an individualized transgression, the result of some expression of free will and/or pathology. As such, the suppression of crime is achievable only through the incapacitation and reformation of individual *criminals* who are abstracted as vastly different from *noncriminals*. Such a dichotomized construct negates more expansive conceptual frameworks that analyze structures of power in the identification of crime and criminality. As Angela Davis and Dylan Rodriguez concede, the label of *criminal* is utilized foremost as an expedient political justification for the warehousing of increasing numbers

of poor, disenfranchised, and displaced persons of color. Abolitionism interrogates the very ontological reality of crime, destabilizing its commonsense definitions and applications while not losing sight of the ways that harm occurs in interpersonal contexts. Excavation of the discursive logics that guide criminal justice reveals retributive penalty, as Mike Davis relates, to be an essential function in the *disappearing* of social problems through the shifting of culpability for social inequities and injustice from dominant processes of oppression onto those deemed *criminal*. In its insistence on deconstructing crime, abolitionism recognizes the broader social arrangements and disparities in power that find expression in and are sustained through criminalization and retributive methods of punishment, which are themselves often utilized as responses to or preclusions of organizing and social movement.

Abolitionists' wariness about terms defined by the state, such as crime, and processes carried out by the state, such as criminalization, does not mean that abolitionists minimize the impact of conflict and harm. On the contrary, conflict plays a pivotal role in abolitionist thought and action. Through its development of and interest in alternative processes such as transformative and restorative justice, abolition centers community, victim, and perpetrator in considerations of harm. Abolition further unsettles commonsense understandings around crime and punishment by responding to questions such as "What do you propose instead?" with answers that avoid the trap of offering a replacement conceptual edifice to fill the footprint of the prison and instead insisting on funding the social wage as an *alternative* to criminalization and punishment. Abolitionism therefore contests state violence as the way to deal with injurious behavior, notes how commensurate instances of harm take place every day that avoid the attention of the state and are resolved by communities and individuals, and raises deeper questions about the nature of the social structure.

Nonreformist Reform and Abolition Democracy

Although abolitionists openly contest the social order and the role of the prison therein, abolitionism as a movement does not claim to behold a

perfect replacement for the system as it stands. Rather, as Mathieson relates, abolitionism is a continual process that will always be unfinished insofar as abolitionism means to present a challenge that is undefinable in the commonsense terms of the established social order. In action and practice, an abolitionist framework does indeed seek a vision often cited as utopian or impossible but asserts the achievability of this position through carefully envisaged *nonreformist* reforms that work incrementally toward abolition. As opposed to expansionist reforms, which seek to preserve the system and its attendant logics, non-reformist reforms strive for the constant erosion of both. At the same time, these reforms are conceptualized as pieces of a broader movement to eradicate other forms of social injustice and toward what Davis, following William Edward Burghardt Du Bois, calls *abolition democracy*. Within the approach of abolition democracy, prison abolition is as much about the eradication of carceral institutions as it is about creating the kinds of structures and relationships that actually solve the kinds of social problems for which the prison serves as a surrogate *solution*. Crucially, the aim of prison abolitionism is not simply to secure a more just system for resolving harm and violence but rather to build a more just *society* that renders the prison obsolete.

Abolition in Practice

Prison abolition has developed and deepened through scholarship but its presence as an available political analysis is due largely to social movement organizations. The International Conference on Penal Abolition (ICOPA) confronts directly the retributive methods that prevail within criminal justice and has built an international movement toward the pursuit of transformative justice. A Toronto-based organization, ICOPA was founded in 1983 by the Quaker Committee on Jails and Justice to advocate for penal abolitionism through primarily faith-based approaches but today incorporates a wider breadth of initiatives rooted in both historical experience and social science research. Committed to the development of pervasive alternatives to imprisonment, ICOPA hosts biannually a worldwide forum to discuss the politics and practices of abolition. The

organization aims to not only trouble commonsense understandings of criminality but also works to complicate the continued expansion of industry in the form of state, nonstate, and nonprofit sectors that have been developed to serve the widening carceral net.

In the United States, Critical Resistance (CR) has been at the front of a movement to realize abolition through disrupting the common sense of police and imprisonment and implementing visionary, practical, and community-based projects. Founded in 1997 by activist-scholars such as Angela Davis, Ruth Wilson Gilmore, and Rose Braz, CR began as a national conference and developed into an organization devoted to the formation of strong alliances in mobilizing against the prison industrial complex. Those involved in CR include a wide range of activists and academics, formerly and currently incarcerated prisoners, labor leaders, religious organizations, educators, policy makers, families, and communities, all of whom are dedicated to the unification of their struggles through efforts to end mass imprisonment and erode the prison industrial complex.

With regional chapters based in several U.S. cities, CR's works include numerous projects that merge the theoretical insights of abolitionism with practical application. One such endeavor is the Abolitionist Educators Campaign, which mobilizes those working in classrooms to work with CR to make abolition discussable in schools and communities, particularly by highlighting how widespread divestment in public education has been integral to the neoliberal state's allocation of resources to police and imprisonment. CR has also partnered with INCITE! Women, Gender Non-Conforming, Trans-people of Color Against Violence toward the development of holistic strategies and mechanisms that address the harms caused by widespread forms of violence. In this way, CR, ICOPA, and other abolitionists build coalitions with many others in developing radical ways of defining and enacting safety and justice, destabilizing the terms' predication on police and imprisonment while building capacity to realize their radical potential by addressing harms and transforming the structural conditions that produced them.

PRISON GANGS, MAJOR

The United States' prison system is populated by several prison gangs. Prison gangs are organizations of prisoners that engage in criminal behavior and activities within the prison system complex. Prison gangs often create external extensions of their prison gang into street gangs that engage in criminal activities outside the U.S. penal system as a support apparatus.

Generally, a prison gang features characteristics that are shared among several prison gangs. Some of these commonalities are having an organized hierarchical structure or strict rules of conduct established by the gang for members to follow.

Another prominent feature of most prison gangs is that they are based on racial lines of exclusion and inclusion. Typically, these prison gangs are established along racial and ethnic lines as prisons are heavily segregated due to racial and social problems that can coalesce and be heightened within a prison system. While there is an abundance of prison gangs in the U.S. prison systems, a selected few stand out as major, being large and particularly important.

Ñeta

Ñeta is an international Puerto Rican prison and street gang. It was founded in the 1970s by Carlos Torrez Irriarte (also known as *La Sombra*, or *the Shade and Maximum Leader*) in Oso Blanco Maximum Security prison (located in Rio Piedras, San Juan, Puerto Rico) to fend off violence between unaffiliated prison members and prison gangs. It has also been called a prisoners' rights group and inmates' rights movement by members and has been known to project political ideas about Puerto Rican independence.

Ñeta is known to use the Puerto Rican national colors and Puerto Rican apparel to signify membership. In the United States, members predominantly reside in the New York/New England area but are spreading to places such as Florida. Ñeta does not have known ties to any other large prison gangs. Law enforcement and departments of corrections have documented criminal illegal activities such as drug activity, violence, extortion, and murder. Ñeta members have also been known to be employed as hit men for other prison and street gangs.

Aryan Brotherhood (AB)

The AB was formed in the 1960s in San Quentin, a state prison in California. The AB uses strong White nationalist and neo-Nazi symbols to illustrate membership. For instance, they employ the use of swastikas, SS lightning bolts, and also 666. They also employ the use of Celtic or Irish cultural symbols. The AB requires a *blood in, blood out* oath from members, which stipulates that an initiate must kill or assault someone to enter the gang and can exit the gang only through death.

The AB is considered the oldest White supremacist prison gang in the United States and has chapters throughout the United States. It is primarily focused on criminal economic activities that are comparable to American organized crime. The AB has been involved in drug trafficking, extortion, murder, and murder for hire. It also has a standing alliance with the Mexican Mafia and a strong rivalry with the Black Guerrilla Family.

Black Guerrilla Family

The Black Guerrilla Family was also formed in the 1960s in the San Quentin state prison in California. Black Panther Party member George Jackson formed the prison gang as a radical revolutionary group that espoused Marxist political philosophy. It is also considered to be an antigovernment gang that advocates for the overthrow of the U.S. government and has had ties to the Black Liberation Army and the Symbionese Liberation Army. Its symbols feature the letters BGF, 276 (which represent the respective letters of the alphabet that symbolize BGF), a dragon surrounding a prison tower, and crossed sabers or guns. The Black Guerrilla Family requires a strict lifelong membership and has a strong rivalry with the AB as well as an alliance with Nuestra Familia.

Mexican Mafia

The Mexican Mafia, also known as *La Eme*, was formed by juvenile Hispanic prisoners in the late 1950s in the Deuel Vocational Institution in San Joaquin County, CA. Although the prison administration attempted to dismantle the Mexican Mafia by sending members to various other prisons such as San Quentin, this had the opposite intention: It empowered and facilitated the growth of the prison gang. The gang has a strict *blood in, blood out* code, and the number 13 is significant to members because the letter M is the 13th letter of the alphabet.

The Mexican Mafia is not only one of the most powerful prison gangs in California but across the United States. Its members engage in drug trafficking and extortion and maintain control within the prison system. They also maintain several connections to street gangs that support economic illegal

ventures initiated by the Mexican Mafia. The Mexican Mafia has an alliance with the AB.

Prison Gang Issues

Departments of corrections and law enforcement agencies face several issues when dealing with prison gangs. Criminal activity and illegal capitalist enterprises are the chief activities of prison gangs as the primary purposes for their existence. These criminal activities are not only present within the confines of the prison complex system but also branch outside to the street level, connecting with street gangs as extensions of the criminal enterprise. One example is drug trafficking, whereby the street gangs take on the role of transporting and distributing narcotics, while the prison gangs act as the hub for information and activity for the street-level drug activity.

Law enforcement also faces difficulties identifying gang members and activity as most prison gang members are sworn to secrecy, use secrecy when facilitating illegal activity, and use cryptic codes and created and unfamiliar languages to communicate. Many law enforcement and corrections agencies use the term *security threat groups* rather than *prison gangs* in an effort to minimize the power and recognition that the term *gang* connotes in society. Such agencies are also aware of alliances and rivalries between various prison gangs and have to keep intelligence current in order to understand the interactions of prison gangs. This intelligence is used not only to curtail activity but also to prevent violence against prison gangs within prisons.

PRISON GANGS AND SECURITY THREAT GROUPS

From a historical standpoint, prison gangs first emerged in the 1950s in Washington State. Their purpose was to provide social support among inmates and to provide protection from persecution and abuse by more predatory inmates or groups of inmates. After emergence in Washington, additional and separate prison gangs formed in other states such as California, Illinois, and Texas in the 1960s. In 2011, the National Gang Intelligence Center estimated that 230,000 gang members were incarcerated in federal and state prisons. If the behavior of any inmate group behavior poses a threat within the correctional environment or threatens to disrupt prison control, the group may be labeled as a strategic threat group. This entry focuses on prison gangs and strategic threat groups as well as on prison management strategies related to these groups.

Prison Gangs

For the most part, prison gangs form along racial, cultural, ethnic, religious, political, or geographic lines (i.e., former place of residence). Once a prison gang grows in members and power, the focus of prison gangs shifts from protection and social support to prison gang criminal profits. The prison gangs are profit oriented and become criminal enterprises that regularly conduct criminal activities such as extortion; sale of protection services; debt collection; bootlegging; gambling rackets; and smuggling of tobacco, alcohol, drugs, food, clothes, video games, computer tablets, and cell phones inside prison walls.

Definition

There is no uniform definition of the term *prison gang*. Federal and state jurisdictions differ on the number of individuals required for a prison gang, whether the gang formed inside or outside prison walls, the degree and nature of deviant or criminal activities, and whether the group has been *validated* according to a set of identified prison gang criteria. However, most definitions of what constitutes a prison gang include the following criteria:

- three or more incarcerated individuals
- who recurrently commit deviant or criminal activities and
- the activities of the group responsible for the deviant or criminal act are known.

In contrast, the American Correctional Association limits the definition of a prison gang to include only gangs that formed inside prison walls. For example, the Aryan Brotherhood and the Black Guerrilla Family both originated within prison walls and would qualify under the American Correctional Association definition of a prison gang. However, the more restrictive American Correctional Association definition would not include the Bloods, Crips, or Latin Kings since those gangs first emerged as criminal street gangs and later migrated to prison once a sufficient number of the street gang members were incarcerated.

However, the distinction of whether the prison gang originated in prison or on the streets is not particularly useful when determining the threat level of a prison gang. Prison gangs that emerged within prison walls and gangs that migrated from the streets are both disruptive and potentially threatening to correctional officials. Both forms of prison gangs, regardless of origin, are powerful prison subcultures that control conduct among select subgroups of prison inmates.

Most prison gangs, whether established in prison or on the streets, have established alliances with criminal street gangs. In return for protection services, the allied street gangs pay *taxes* (i.e., a percentage of the street gang's profits) to the prison gang and carry out orders received from prison gangs. Often, these orders facilitate control of drug trafficking and other criminal operations conducted by the street gangs as well as smuggling of contraband inside prison walls. As such, the distinction of where the prison gang first emerged is not particularly useful when determining the degree and nature of criminal activity orchestrated by the prison gang.

Instead of tracing the roots of a prison gang, an alternative classification that might be more useful for determining the threat level of a prison gang is based on the nature and degree of power exhibited by the prison gang. Factors that could be of paramount importance include the following:

- strength of the prison gang in terms of gang members, prospects, and associates
- territorial control (i.e., migration) of the prison gang to other federal or state prisons
- the number and strength of allied criminal street gangs
- the nature and degree of criminal activities committed on behalf of the prison gang
- the regional, national, or international scope of criminal activities committed on behalf of the prison gang
- the degree and sophistication of organization and leadership of the prison gang
- the disruptive nature and perceived degree of threat perceived by correctional officials

Psychological Underpinnings That Support Prison Gang Membership

To understand the psychology of joining a prison gang, one must understand the nature of incarceration. The inmate is literally stripped of personal belongings, is assigned a number, has restrictive contact with family or friends, and is physically moved to a new residence that is often shared with a violent or socially deranged stranger. Understandably, this can result in feelings of isolation, fear, and loneliness.

One response is to join a prison gang. Membership in the prison gang offers protection from predatory inmates, social support, and access to a broad array of contraband not enjoyed by other inmates. Collectively, this helps to reduce if not eliminate the feelings of fear, isolation, and loneliness associated with incarceration.

In essence, the prison gang becomes the inmate's new family. This solidarity is reflected in the fact that most prison gangs require new members to relinquish positions of leadership status in the former street gang as a sign of loyalty to the prison gang. In addition, the new member is required to put aside any street gang rivalries or conflicts as a condition of membership in the prison gang.

This loyalty and solidarity continues once the prison gang member is released from prison. Upon release, the prison gang member may reconnect with his former street gang and may assume a position of power and leadership in the criminal street gang due to enhanced status associated with

prison gang membership. In some instances, the released inmate becomes the *tax collector* for the prison gang who collects a portion of the street gang's criminal profits as payment for protection services, should members of the street gang be sentenced to prison. This symbiotic relationship creates a revolving door whereby not only prison gang members rejoin former gangs on the streets but also newly incarcerated street gangsters provide a never-ending source of new prospects for the prison gang.

Prison Gang Subculture

Prisons, by their very nature, contain many violent subcultures. It is a place where civilized society sends those who deviate from the norms of society. It is a place that warehouses murderers, rapists, thieves, and other social outcasts. As a result, inmates tend to band together for protection and social support. In large prisons, this results in differing subpopulations often aligned along racial, ethnic, cultural, religious, political, and former geographical ties. This leads to the creation of racially and ethnically divided subgroups, which evolve into prison gangs such as the Mexican Mafia (Hispanic), the Aryan Brotherhood (Caucasian), and the Black Guerrilla Family (African American). When these groups grow, the prisons are controlled, in varying degrees, by the inmate subpopulations and prison gangs.

Since the mid-1950s, subpopulations and prison gangs have evolved into highly structured business entities. To maintain control of criminal enterprises, prison gangs can be extremely violent. They are willing to commit crimes of assault, battery, and even murder to retain profits received from protection services, extortion, gambling, and smuggling of contraband such as drugs, alcohol, cigarettes, cell phones, and weapons into prison. Similarly, prison gangs control a number of allied street gangs that are willing to commit acts of violence on behalf of the prison gang in order to maintain drug trafficking and other criminal operations conducted outside prison walls.

The control of criminal activity by street gangs often starts as payment of *taxes* in return for protection services if and when members of the allied street gang become incarcerated. But the protection services also extend to protection outside of

prison walls as the prison gang often orchestrates large drug trafficking operations among allied street gangs. This extrajudicial control over allied street gangs is accomplished by use of smuggled cell phones and messages carried from inside prison walls by visitors with street gang connections. Should any allied street gang not follow orders, the prison gang merely issues a *green light* for all prison gang members and all allied street gangs to beat or even murder any disobedient members or disrespectful rival gang members.

Organizational Structure

Prison gangs differ in terms of organizational structure. Some prison gangs are large and are highly structured while other prison gangs may lack strength of membership or any clearly defined leadership hierarchy. But all gangs have shot callers. The shot caller may be a single powerful gang member or a coalition of gang members who acts collectively to call the shots (i.e., determine activities and policies). Some prison gangs enjoy military-style leadership with generals, lieutenants, sergeants, and soldiers, while other prison gangs spread leadership decisions through a more democratic process in order to avoid disorder should a shot caller be transferred or killed by a rival gang.

With growth, a prison gang may spread to other prisons. If the gang emerged from inside prison walls, it may also become a criminal street gang. Similarly, a street gang may also become a prison gang if enough gang members become incarcerated. As the prison gang grows, it naturally develops alliances with street gangs to facilitate criminal operations (e.g., drug trafficking) conducted both inside and outside prison walls. In some instances, the prison gang may conduct criminal operations on a regional, national, or even international level, thus increasing the nature of its threat inside and outside prison walls.

Major Prison Gangs

As noted, prison gangs are often aligned along racial, ethnic, cultural, religious, or political ties. For example, the Aryan Brotherhood is composed of White Supremacists, the Mexican Mafia is primarily composed of Hispanic or Mexican

Americans, and the Black Guerilla Family is composed of African Americans who subscribe to Marxist–Lenin political beliefs. In contrast, a few prison gangs, such as the Consolidated Crip Organization and the 18th Street gang, allow membership of mixed races.

A few criminal street gangs, such as the Bloods, Crips, or Norteños, have enough incarcerated gang members to form gang sets within prison walls. Other street gangs, however, are not large enough to form a gang within prison walls and are forced to seek protection afforded by an established prison gang, such as the Mexican Mafia.

Prison gangs in the United States include the Aryan Brotherhood, Asatru, Black Disciples, Black Guerilla Family, Black P. Stone Nation, Border Brothers, Crips, European Kindred, Fruits of Islam, Gangster Disciples, Indian Brotherhood, Insane Gangster Disciples, Ku Klux Klan, Nuestra Familia, Latin Counts, Latin Kings, La Raza, Little Rascals, Los Solidos, Maniac Latin Disciples, Mara Salvatrucha (MS 13), Mexican Mafia, Mexicanemi, Ñeta, Norteños, North Side Villains, Nubian Islamic Nation, Odinists, Simon City Royals, Skinheads, Sons of Samoa, Spanish Cobras, Sureños, Syndicate Nuevo Mexico, Tango Blast, Texas Syndicate, Tiny Rascals, United Blood Nation, Universal Aryan Brotherhood, Vice Lords, and White Supremacists.

Prison Staff

Some correctional officers assist prison gangs in their criminal activities—for example, smuggling drugs, cell phones, or other contraband in return for money, sex, and protection. Similarly, some officers may become involved in money-laundering operations, prostitution, and delivering messages between inmates and gang members outside prison walls. Corrections staff are traditionally underpaid, so they may be subject to intimidation and bribery by prison gangs. In the eyes of some guards, cooperating with prison gangs is better than the alternative of being threatened, harassed, or accosted by prison gang members.

Security Threat Group

As noted earlier, some inmate groups may be labeled as strategic threat groups. Although there

is no universal definition, a strategic threat group is generally characterized as

- a group of three or more inmates who were members of the same street gang, prison gang, or extreme political or ideological group
- with recurring patterns of threatening or disruptive behavior such as gang violence or violations of prison rules or regulations and
- who pose a threat to prison authority and control.

The primary characteristic of a strategic threat group is that the group becomes a security threat within the correctional setting. The threat may include threats to an adversarial prison gang, group violence, the ability to incite a riot, the ability to inflame racial or political attitudes, or the ability to commit gang-related crimes.

For example, the Arizona Department of Corrections defines a strategic threat group as

[a]ny organization, club, association or group of individuals, formal or informal (including traditional prison gangs), that may have a common name, identifying sign or symbol, and whose members engage in activities that would include, but are not limited to planning, organizing, threatening, financing, soliciting, committing, or attempting to commit unlawful acts or an act that violates the departments written instructions, which would detract from the safe, orderly operations of prisons. (Arizona Department of Corrections, 2018)

As indicated, large numbers is not an essential element of a strategic threat group. In fact, the CCA defines a strategic threat group as any group of two or more individuals that is disruptive or threatens prison order.

Strategic threat groups may have a common name or symbol, and most do. But a common name or symbol is not required. In contrast, a pattern of gang-related deviant or criminal behavior is required. A strategic threat group must exhibit behavior that breaks prison rules, is illegal, or deviates from prison norms. In addition, the strategic threat group must exhibit a pattern of disruptive, illegal, or deviant behavior.

Validation of Prison Gangs or Strategic Threat Groups

Validation is the process by which an inmate is determined to be a prison gang member or a security threat group member by prison officials. To be validated, the inmate must meet a set of prison criteria that generally includes documenting a pattern of abuses or offenses such as repeated violations of disciplinary rules, assaults, violence, or other disruptive acts over a period of time. Validated gang members, or *stigged* (i.e., stigmatized) inmates, may lose certain privileges or be given more restricted housing environments.

Strategies for Management

Many strategies have been tested to reduce prison gang membership and decrease strategic threat groups. One strategy is to break up prison gangs by scattering their members to various prisons or higher security institutions. The idea is to divide and dilute the gang membership. However, this strategy seldom serves to destabilize the prison gang or security threat group. Instead, it tends to spread the prison gang or security threat group to other prisons, thereby creating a broader base of recruiting and control for the prison gang or security threat group. It also serves to strengthen a prison gang or security threat group by seeding membership in multiple prisons, and in some cases, multiple states.

Another strategy is to segregate prison gang or security threat group members from the rest of the inmate population. Generally, this is difficult if there is a possibility that the prison gang will interact with other inmates in the yard, working quarters, or the cafeteria. It can also lead to large-scale prison race riots.

Balancing the number of rival gang members in each prison unit is aimed at minimizing power or control by one particular prison gang. However, balance is difficult to obtain as prison gangs are constantly recruiting new prospects and associates. Similarly, to minimize power and control of a prison gang, behavior modification—that is, removing privileges for bad behavior may be removed and bestowing privileges for good behavior may be initiated. However, smuggling of contraband often defeats such attempts of rewards and punishment.

Isolation may also be used as a management strategy and is accomplished by eliminating communication channels, such as gang mail, and abolishing gang colors within prison walls. This may also be coupled with increased intelligence and information systems designed to track and monitor prison gang and security threat group activity.

Gang renouncement and disassociation programs are designed to facilitate abandonment of gang membership and accommodate any gang members who want to leave the gang lifestyle or testify against gang members.

Finally, new and increased sanctions for crimes committed inside prison walls may be instituted. These include enhancements for repeat offenders or crimes committed by validated prison gang or security threat group members. The new crimes might include recruiting of new prison gang members, selling drugs while incarcerated, or possession of improvised weapons inside prison walls. Similarly, penalties might be enhanced for prison offenses such as protection rackets, extortion, or prison gang fights.

Conclusion

As the United States incarcerates more individuals and increases average sentences, and as prison gangs orchestrate criminal activities both inside and outside prison walls, the number of prison gangs and strategic threat groups will continue to grow. With criminal activity becoming institutionalized behind prison walls, researchers may want to examine whether the goals of incarceration remain effective, especially in an environment where enhanced Internet and cell phone communication systems behind prison walls may help such criminal activity to flourish.

PRISON MISCONDUCT, PREDICTION OF

Every correctional system has a codified set of rules that inmates must follow. Whenever an inmate is accused of prison misconduct—that is, breaking one of these rules—he or she will appear before a disciplinary hearing officer or panel. At the due process hearing, the inmate can provide evidence supporting his or her innocence and has the right to appeal the decision of the disciplinary hearing officer to a higher authority. If the inmate is found guilty of the infraction, he or she will be punished. Common sanctions an inmate might receive include extra duty, loss of privileges, loss of good time, disciplinary segregation, or a disciplinary transfer to a higher security institution.

Predicting prison misconduct is important for several reasons. First, it can be of value in classifying inmates. Inmates at elevated risk of prison misconduct should be assigned to a higher security institution where there is more structure and greater security. Second, it can be of assistance in managing inmates. Inmates at high risk of prison misconduct should receive more attention and

program referrals than inmates at low risk of prison misconduct. Third, it can be helpful in identifying features of the correctional environment that encourage prison misconduct and thus need to be changed or addressed in some manner.

Characteristics of both the inmate (personal domains) and prison (situational domains) have been examined in research on prison misconduct. Some of the principal personal and situational domains that predict prison misconduct and violence are briefly described in the next several sections.

Personal Domains

Basic Demographics

Younger inmates, male inmates, and inmates serving shorter sentences are more likely to engage in prison misconduct than older inmates, female inmates, and inmates serving longer sentences. Age, gender, and sentence length may interact in that younger male inmates serving shorter sentences are at greater risk of prison misconduct in male institutions, whereas older female inmates serving longer sentences are at greater risk of prison misconduct in female institutions.

Prior Misconduct

One of the best predictors of future behavior is past behavior. Consequently, an individual with a prior history of violence and misconduct in jail and prison is at increased risk of future violence and misconduct. A prior history of criminal offending also predicts prison misconduct but not as well as prior prison misconduct.

Mental Illness

Inmates with active symptoms of mental illness are at elevated risk of prison misconduct, although it depends on the symptoms. Psychosis, depression, and paranoia are more likely to be associated with prison misconduct than anxiety.

Peer Affiliations

Associating with a deviant peer group in prison has been found to predict prison misconduct. Those inmates who associate with fellow

prisoners who commit prison infractions and violence are themselves more likely to engage in prison misconduct and aggression. Gang membership also places an individual at increased risk of prison misconduct. Research indicates that affiliating with a gang is a powerful risk factor for institutional misconduct and violence and that core gang members are several times more disruptive and violent than peripheral gang members.

Criminal Thinking

Criminal thinking or antisocial cognition is another personal domain predictor of prison misconduct. There is evidence that criminal thinking may mediate the relationship between static risk factors such as age, criminal history, and gang affiliations, on the one hand, and prison misconduct, on the other hand.

Situational Domains

Security Level

Higher security-level institutions have more trouble with serious disciplinary infractions and violence than lower security-level institutions, but there is no consensus as to whether this is due to characteristics of the institution or characteristics of the individual. Prison misconduct could be a reaction to the oppressive structural features of higher security institutions (deprivation) or a reflection of greater criminal propensity and stronger antisocial attitudes in inmates assigned to higher security institutions (importation). One group of researchers, in fact, randomly assigned inmates to either a low-security or medium- to high-security institution and discovered that there were no differences in misconduct between inmates in the two prisons.

Prison Overcrowding

It is generally assumed that prison overcrowding leads to increased misconduct and violence, and while several studies have shown just this, a meta-analysis of 16 studies found no compelling evidence of a relationship between prison overcrowding and misconduct. It has been speculated that correctional systems respond to overcrowding by implementing corrective measures that

then stabilize or actually reduce the level of misconduct in prison.

Direct Supervision

Direct supervision involves the use of smaller housing units organized into pods that allow better surveillance by the unit officer than the traditional linear cell house. This approach to supervision has been found to be effective in reducing misconduct and violence in jails and prisons.

Program Availability

Prisons with fewer programs and work opportunities are often plagued by higher rates of misconduct and violence. This finding can be interpreted in one of several ways. First, correctional programs may reduce disciplinary infractions by teaching inmates self-control. Second, correctional programs may discourage prison misconduct by keeping inmates busy. Third, low- and medium-security institutions house inmates less likely to violate the rules of the institution and are also where the majority of correctional programs are located.

Ambient Temperature

Prison misconduct has been found to be more common during the warmer months of the year, particularly when the ambient temperature is up around or exceeds 90°F.

PRISON OVERCROWDING

Overcrowding in prisons has been considered an issue since the development of the modern prison; yet, it has evaded simple definition because there is no international consensus about how to measure it. The term *prison overcrowding* is most commonly used to describe a situation in which the population of a prison exceeds the capacity that it was designed to house. This, however, lacks a rigorous analysis of the many nuances that require consideration.

This entry begins by presenting some of the ways in which prison overcrowding is generally understood and measured and considers how it can be viewed as arising at a point where a number of criminal justice policies intersect. These include, for example, the role of the criminal justice system, attitudes toward prison sentencing, alternatives to custody, the provision of health care to prisoners, and access to rehabilitation services. The effects of prison overcrowding, as well as initiatives that address the issue, are also considered.

The Growing Prison Population

It is generally agreed that the prison population is growing in the majority of countries throughout the world. It is also generally accepted that overcrowding negatively affects prison systems and has the potential to impact upon delivery of health care, education, and rehabilitative services that characterize a modern prison. The trend must be understood in terms of the factors that contribute to the increase in the prison population, the

potential societal cost, and the resulting financial burdens placed on governments.

A more pressing concern is that prisons in many cases are accommodating more prisoners than they were originally designed to house. A number of countries are reported as having a prisoner occupancy rate higher than 120%, with some as high as almost 400%. It must be remembered, however, that the overcrowding rate is not an indicator for the actual problems and conditions faced by overcrowded prisons. It should also be noted that a simple comparison of overcrowding could be misleading and fail to consider other issues that have contributed to the situation. One reason for the use of such statistics is that it is the only quantifiable measure that can be used to provide an indication and analysis of overcrowding within one country as well as enabling comparison between countries.

A Question of Space

Although there is no internationally accepted standard for the minimum space requirement for each prisoner, attempts have been made to qualify what constitutes an acceptable level. The United Nations (UN) Standard Minimum Rules for the Treatment of Prisoners, for example, state that prisoners should be provided with accommodation, particularly where they sleep, that meets their health needs. This includes floor space that corresponds with international recommendations, fresh air, ventilation, heating, and lighting.

Similarly, the guidelines provided by the International Committee of the Red Cross (ICRC) suggest that the minimum space required is 5.4 square meters per person in a single cell or 3.4 square meters per person in a shared cell or dormitory, including where bunk beds are used. In addition, the ICRC argues that the appropriate amount of space required cannot be measured by space alone and should include consideration of the following factors:

- condition of the building
- amount of time prisoners spend in the sleeping area
- number of people in that area
- other activities occurring in the space
- ventilation and light

- facilities and services available in the prison
- extent of supervision available

The ICRC argues that including more of the aforementioned factors will result in a more accurate measure of the impact of overcrowding, on both prisoners and staff. It is generally acknowledged that, currently, prisoners do not have the minimum space required as recommended by the ICRC and that the reality for many prisoners involves spending long hours in overcrowded, cramped conditions.

Causes for Prison Overcrowding

There are numerous and varied reasons to explain prison overcrowding. Rising prison populations can be due to changes in the law, policy, and sentencing practice by the courts; the length of sentences; a lack of investment in prison building programs; and a lack of prison locations due to age and deterioration of prison buildings. In some countries, where the overall rate of imprisonment is comparatively low, prisons in urban areas or situated close to the courts can still be overcrowded. Predetention prisons in particular may have very high levels of overcrowding.

A lack of investment in prison facilities can impact the provision of rehabilitation programs and result in higher rates of recidivism. There may be a lack of resources to fund preventive general and mental health care for vulnerable prisoners, such as those with problematic drug and/or alcohol use, those with learning difficulties, and those with mental health problems. As a result, prisons may become a place where vulnerable groups are held without effective treatment to meet their needs. This has the potential to lead to a cycle of reoffending and imprisonment, which in turn contributes to overcrowding.

Greater use of custodial sentences, resulting from a lack of knowledge relating to alternatives to custodial sentences, can contribute to overcrowding. There may also be a lack of investment in measures such as electronic tagging and community sentences. In some countries, people may be in prison for lengthy periods prior to going on trial, and nonviolent, vulnerable prisoners (e.g., problematic drug users, those with mental health

problems, and individuals with learning disabilities) may receive tough sentences.

Changes in policy, including greater use of imprisonment, longer sentences, and in many European countries, more restricted use of parole or conditional release, are also factors that have influenced the growth in the prison population in certain countries. Often, these changes occur as a result of a desire to respond to public perceptions of the role of the criminal justice system.

Why Large Prison Populations Matter

Prison overcrowding has the potential to impact the quality of health-care services provided, nutrition, sanitation, and the care of vulnerable groups. Effective prison management can also be compromised when there is a lack of space, making it more difficult to deliver rehabilitative, educational, cultural, recreational, and religious activities. The physical, mental health, and well-being of all prisoners can also be affected, with the potential to exacerbate existing conditions and, at the worst extreme, generate prisoner tension and violence. There is growing acknowledgment from international bodies that overcrowding is a key impediment to the implementation of Standard Minimum Rules for the Treatment of Prisoners in prisons. Overcrowding makes it harder for prison administrations to maintain or guarantee humane conditions that meet recommended international standards and guidelines.

Overcrowding has the potential to negatively affect prison staff working in a variety of areas within the institution. Staff may find, for example, that they have insufficient time to deal with prisoners' problems and struggle to provide a positive environment that promotes rehabilitation. Provision of health care that is equivalent to that available in the community may also become more challenging. Other professional groups (e.g., educators, psychologists, social workers) may struggle to deliver key services to meet the needs of individuals in an overcrowded prison. An increase in prisoner numbers also has the concomitant effect of lowering the staff-to-prisoner ratio and can increase the potential for conflict. All these factors combined can lead to a more dangerous and stressful working environment for prison staff and prisoners and act to lower staff morale.

Solutions

If it is accepted that loss of freedom is the primary punishment for prisoners and that imprisonment should not impinge on individuals' human rights, then it becomes apparent that overcrowding in prison is an issue that needs to be addressed. Initiatives to reduce the numbers in prison could involve greater use of diversion schemes and alternatives to custody for those with problematic drug use or offenders with mental health problems. There is a wide range of alternatives available in many prison administrations, including, for example, supervision by probation services. Measures such as conditional and suspended sentences have the potential to contribute to the reduction of prison populations and do not require major investments to implement. Similarly, cutting the amount of time people spend in prison on remand, making court procedures quicker, and using shorter sentences can act to reduce the number of offenders in prison. It is recognized, however, that countries are in different states of development with respect to their judicial and penal systems and may not be in a position to consider or implement some of these.

Plans to reduce overcrowding that build on the relevant international instruments have been developed. These include the Standard Minimum Rules for the Treatment of Prisoners, the UN Standard Minimum Rules for Non-custodial Measures (also known as *the Tokyo Rules*), and the UN Rules for the Treatment of Women Prisoners and Non-custodial Measures for Women Offenders (also known as *the Bangkok Rules*).

Reducing the size of the prison population could be achieved by a number of means. These include legislative change and the manner in which probation, community sentences, and alternatives to custody for young people and parents with dependent children are used. However, it is recognized that such measures require both creative thinking and political will to achieve.

Legislative Change

Increasing parole boards' authority for early release for prisoners who pose little danger to society may have a major impact on overcrowding. Providing restrictions on the use of pretrial detention to cases where offenses are particularly

serious or where it is not in the public interest to leave the accused in the community, regulating the amount of time allowed for the investigation period (in many countries this can be a very lengthy process), and improving access to justice at the point of pretrial detention particularly may reduce overcrowding, especially in those countries with high levels of overcrowding. Making a variety of alternative noncustodial measures and sanctions available to the courts might help to reduce the use of pretrial detention and imprisonment.

The use of mobile judges holding hearings in the prison may also reduce the number of prisoners kept in pretrial detention. Amnesty for less serious offenders who are nearing the end of their sentences can be an effective short-term measure.

Use of Probation, Alternatives, and Community Sentences

Increased use of probation may impact overcrowding, although not all countries have a functioning probation service. A wider application and utilization of the UN Standard Minimum Rules for Non-custodial Measures (the Tokyo Rules) on alternatives to imprisonment may reduce overcrowding. Using diversion from the criminal justice system, such as police warnings, cautions, mediation, referral to drug treatment or mental health services, and promoting the use of early release procedures (e.g., conditional release), might also be effective. Although there is no current concrete evidence that restorative justice has led to a reduction of the prison population, research indicates that as it becomes more widely used as an alternative to criminal justice procedures, it will create the conditions in which earlier release becomes possible.

Alternatives for Young People and Parents With Dependent Children

Using alternatives that focus on education and restorative measures for young people and keeping the use of custodial sentences to a minimum may also impact overcrowding. The Bangkok Rules suggest that noncustodial measures are a preferred option for pregnant women and children's sole or primary carers when sentencing or deciding on

pretrial measures. Custodial measures are used as a last resort for serious or violent offenses.

In addition to these measures, further reductions could be made to the prison population by utilizing alternatives to custody for groups who have special requirements. This can include, for example, female prisoners, prisoners with health-care requirements, prisoners with drug and/or alcohol addiction, prisoners with learning difficulties, older prisoners, prisoners with disabilities, prisoners from ethnic minorities, and foreign nationals. As well as reducing the prison population, diversion from custody might deliver the care and treatment needed by these groups that is rarely met in underresourced and overcrowded prisons.

PRISON RAPE ELIMINATION ACT

The Prison Rape Elimination Act (PREA) of 2003 was enacted by the U.S. Congress to protect incarcerated individuals from sexually abusive behavior from both other inmates and from staff. Prior to that time, the general public often considered sexual abuse in prison an inevitability of incarceration. Television shows and feature films depict this type of violence as a common occurrence. With over 6.6 million individuals under the supervision of the U.S. adult correctional systems in 2016 (jails, prisons, lockups, community corrections, and probation), the number of victims of sexually abusive behavior could be astronomical if the prevalence of abuse matched societal expectations of prison life. PREA required the creation of a national commission to study the causes and consequences of sexual abuse in confinement. With the information the commission gathered, standards to prevent, detect, and punish sexual abuse in correctional facilities were developed. These mandatory standards apply to all adult prisons and jails, lockups, juvenile facilities, immigration detention sites, and probation, parole, and community corrections facilities.

Sexually abusive behavior in confinement potentially has dire consequences. The establishment of PREA helps to reduce the occurrence of sexually abusive behavior toward inmates in confinement and ensures that proper intervention occurs when abuse is suspected or confirmed. Starting with a review of prevalence, moving through a definition of terms, and reviewing prevention requirements, response to allegations, and methods to ensure compliance with standards, this entry focuses on PREA as it relates to adult prisons and jails.

Brief Review of Prevalence

PREA requires that the Bureau of Justice Statistics conduct an annual statistical review and analysis of the incidence and effects of sexually abusive behavior in confinement facilities. These statistics include only reported instances and allegations of sexual abuse and sexual harassment. True incident tallies may be higher. According to the Bureau of Justice Statistics' report from 2016, in which

prevalence statistics from 2015 are reported, there were 24,661 allegations of sexual victimization. Despite PREA containing the words *prison rape*, the types of sexually abusive behavior encompassed by PREA involve much more than rape or penetration. In addition to nonconsensual inmate-on-inmate sexual acts (penetration), there is inmate-on-inmate abusive sexual contact (intentional touching of the genitalia, anus, groin, breast, inner thigh, or buttocks either directly or through the clothing), inmate-on-inmate sexual harassment, staff-on-inmate sexual misconduct, and staff-on-inmate sexual harassment. Of the 24,661 allegations of sexual victimization in 2015, 1,473 cases were substantiated or found to have occurred. Approximately 58% of these substantiated cases involved inmate-on-inmate sexually abusive behavior.

Understanding Consent, Coercion, Prison Rules, and PREA

In prison, no sexual activity is permissible. There are rules to prohibit it and sanctions for engaging in such behavior. This is regardless of whether, in the case of inmate-on-inmate sexual relationships, this behavior is consensual. Viewed through the lens of PREA, however, one can distinguish between consent and coercion insofar as whether sexual behavior is acceptable. To illustrate this, consider the case of two inmates being interrupted during sexual activity that they each independently report was consensual. According to prison rules, this activity is unauthorized and would result in an incident report with disciplinary sanctions. However, this would not be a PREA case. PREA specifically focuses on nonconsensual sexual activity between inmates. When the sexual activity is between staff and inmates, it will always be a PREA violation. Even if an inmate pursues a sexual relationship with staff, implying consent, this is sexual abuse. Sexual activity between staff and inmates is always illegal.

Prevention

Prevention of sexual abuse of inmates in confinement is the primary goal of PREA. Prevention, as outlined through PREA, is accomplished through multiple methods. For example, all agencies are

required to adopt, and reinforce through training, a zero-tolerance stance toward sexually abusive behavior by inmates and by staff. In addition, cross-gender viewing of inmates by staff is minimized as much as possible through the use of privacy shower curtains, partitions in bathrooms, and announcements to the inmate population when opposite gender staff enter living quarters. Also, male staff are not permitted to pat-search female inmates except in emergency situations, perhaps something that threatens the security of the institution such as a correctional officer noting an inmate with a homemade weapon tucked in her waistband. To ensure that efforts of this type are implemented, each facility must establish a PREA compliance manager, typically a member of the facilities upper leadership. This person will have oversight for the multiple facets of PREA implementation. In addition, two of the largest efforts in prevention are implemented through training and screening, each of which is reviewed next.

Training

One method of prevention required by PREA is training. General staff PREA training begins during orientation and includes refresher training at least every 2 years thereafter. The training addresses numerous aspects of prevention to include a focus on zero-tolerance policies; instruction on how staff fulfill their responsibilities for prevention, detection, reporting, and response; the dynamics of abusive behavior in confinement; common reactions of victims; how to detect and respond to signs of sexual abuse; how to avoid inappropriate relationships with inmates; and how to comply with the laws related to mandatory reporting of sexual abuse to outside authorities. The goals of such training are preventing abuse and responding appropriately when abuse occurs.

In addition to the general staff training, PREA requires staff who work in specific disciplines within the corrections profession, such as medical practitioners, mental health practitioners, and investigators, to receive specialized training to assist in ensuring appropriate treatment, investigation, and communication with victims and perpetrators of sexually abusive behavior. This reflects the PREA strategy of shifting the culture of

confinement facilities toward preventing and responding appropriately to sexual assault and harassment. It requires a coordinated effort that is anchored through intense interdisciplinary staff communication and cooperation.

Extending out to and through the inmate population is also part of the PREA strategy. PREA training for inmates, much like for staff, begins when inmates first arrive at a facility. Inmates are verbally informed of PREA and are also provided written guidance regarding the agency's zero-tolerance policy and how to report incidents of sexual abuse and/or harassment. Within 30 days of their arrival to the facility, inmates are provided with comprehensive training about their right to be free from sexual abuse and harassment and their right to be free from retaliation for reporting such incidents.

Screening for Risk of Victimization and Abusiveness

An important method to prevent sexual abuse of inmates is to conduct a screening for risk of sexual victimization and risk of sexual abusiveness for all inmates entering a facility. During the initial intake screening, staff use an objective screening instrument to determine if an inmate may be at risk. Medical or mental health practitioners will conduct a full risk determination if inmates are determined to potentially be at risk.

Janet Warren and Shelly Jackson conducted research on inmate populations to identify risk markers for sexual victimization and abusiveness in male and female inmates. Some of the identified risk markers for sexual victimization in male inmates include having a slight build, being a sex offender, having a history of being sexually victimized in childhood or in prison, being a first-time offender, having a low-level mental illness, appearing fearful or vulnerable, and being homosexual or bisexual. For female inmates, risk markers for victimization include factors such as previously being sexually abused, being extremely fearful of sexual assault, having been neglected or psychologically abused as a child, and having histrionic personality disorder traits of dramatizing and attention seeking. Risk markers for sexual abusiveness/predation in male inmates include a history of sexual victimization/predation in prison; hypersexuality;

hypermasculinity; history of a head injury with loss of consciousness; history of childhood psychological, physical, or sexual abuse; and antisocial personality traits of irritability, aggressiveness, and recklessness. Female inmates' risk markers for abusiveness include hypersexuality, prior sexual predation in prison, prior sexual victimization, and being homosexual. Having one or more of these risk markers does not mean an inmate will be a victim or will be an abuser, but it does elevate the individual's overall risk level and warrants more staff attention to the inmate in an effort to prevent sexually abusive behavior from occurring.

The correctional facility uses the information from the risk screening to inform housing, bed, work, education, and program assignments. The goal is to keep separate those inmates who are at a high risk of engaging in sexually predatory behavior from those who are at an elevated risk of being victimized. Considerations for housing may include transferring an inmate to a different facility or placing the inmate in a housing unit with no inmates deemed to be at risk for the opposite. Bed assignment recommendations may include housing the inmate closer to the correctional officer's workstation or only with a roommate who has the same risk markers. Regarding work and education assignments, the inmate may be assigned these according to level of staff supervision. For example, an inmate at risk of predation may be recommended for a highly visible job during the day shift and no education classes in the evening hours, thereby ensuring greater staff supervision. Programming recommendations may include such options as sex offender counseling or criminal thinking elimination group therapy, among others.

Responding to Sexual Abuse Allegations

If efforts at prevention fail and there is an allegation of sexually abusive behavior, certain actions are triggered to ensure the safety and treatment of the alleged victim, the collection of evidence, and the punishment of the perpetrator. Interdisciplinary cooperation is essential throughout this process. First responders, medical and mental health practitioners, and investigators must all coordinate their response, and in turn, they communicate their findings with the facility's PREA compliance manager.

First Responders

First responders may be any staff at the facility regardless of position. The first responder is the individual who either receives the allegation from the victim or potentially observes the abusive behavior as it is occurring. Following an allegation or identification of potentially abusive behavior in progress, the first responder's immediate action is to separate the victim and abuser. The crime scene, if one exists, is secured so that evidence collection can occur. The alleged victim is asked not to compromise evidence by showering, urinating or defecating, eating, drinking, or washing his or her hands until a forensic medical examination can be completed, if one is needed.

Medical Practitioners

Medical practitioners perform an initial injury assessment and test, when appropriate, for pregnancy, HIV, and other sexually transmissible infections. Post-rape prophylactic medical measures to reduce the transmission of sexually transmitted diseases are also offered. If the local institution medical staff are properly trained in the collection of sexual assault evidence, they conduct the forensic medical examination on site. More commonly, the inmate receives the forensic medical examination outside of the institution at a local hospital where medical personnel have the necessary training. A victim advocate is made available to the inmate during the forensic medical examination, as the evidence collection following a sexual assault can be a traumatizing event.

Mental Health Practitioners

Mental health practitioners at the institution provide crisis intervention, assess the alleged victim's mental status, and conduct an assessment of treatment needs. The alleged abuser also undergoes a mental health evaluation. Victims and abusers are provided ongoing mental health care as clinically indicated. When necessary, referrals for continued care following transfer or release from prison are provided. All treatment services for the victim are provided at no cost in the facility regardless of whether the victim identifies the perpetrator.

Investigators

When a facility conducts its own investigations following an allegation, the investigation must be prompt and thorough. Trained investigative/intelligence staff gather and preserve evidence, including physical, DNA, and electronic monitoring data such as video, phone, or e-mail communication. They conduct interviews of the victim and the alleged perpetrator as well as any potential witnesses.

Upon completion of the assessments and interviews by medical and mental health practitioners and by investigators, the facility PREA compliance manager reviews all findings and determines whether the case should move forward. In some instances, the case will not continue, and a full PREA investigation will not be warranted. Examples of this type of scenario include consensual sexual activity between inmates and an allegation that is blatantly unfounded. An allegation may be blatantly unfounded if, for example, the alleged perpetrator was not at the institution on the day the alleged incident occurred or there is direct video evidence that refutes the allegation.

At the conclusion of all investigations, the allegation is indicated as substantiated, unsubstantiated, or unfounded. A substantiated case means the event was found to have occurred based on the preponderance of the evidence. An unsubstantiated case means the event may have occurred, but there is insufficient evidence to prove it. An unfounded case means that there is evidence the event could not have occurred. Regardless of the case outcome, the alleged victim is notified of the finding.

In substantiated and unsubstantiated cases, the facility conducts an incident review to assess the facility's response to the allegation, what factors may have contributed to the incident, and any recommendations for improvements, such as adding cameras to areas of the institution or increasing staffing levels in a particular department. Typically, upper-level management officials conduct the review with input from key areas such as medical and mental health practitioners, investigators, and other supervisors. With the incident review, the facility moves from response and investigation to identification and correction of potential problem areas, thereby shifting back to

prevention, again demonstrating the importance of prevention in PREA.

Ensuring Compliance

It is insufficient to have standards for protection of inmates if nobody is ensuring that these standards are being followed. At the institution level, the PREA compliance manager has oversight of the program and is responsible for monitoring compliance. At the agency level, there is an agencywide PREA coordinator who oversees agency efforts to comply with the PREA standards. PREA requires all facilities to be audited by an external Department of Justice–certified auditor every 3 years. Among their responsibilities during an audit, auditors review policies and procedures, sample documents (i.e., investigative files), tour all areas of the facility, and interview staff and offenders. Each standard is reviewed to determine if the facility exceeds the standard, meets the standard, or does not meet the standard. A facility is provided a 180-day corrective action period to rectify any procedures that do not meet the standard. A final report is issued and must be published and accessible to the general public on the agency's website.

PREA Impact

The enacting of PREA by Congress in 2003 provided a more comprehensive and systematic approach to sexual abuse prevention and response to sexually abusive behavior of confined individuals than had previously existed. While some agencies and facilities had existing policies and procedures for addressing this behavior prior to the passage and implementation of PREA, the law has helped to ensure that all inmates are protected and treated appropriately through standardized requirements, and it has helped to shift the entire culture of corrections in this domain. It is unacceptable for any inmate to be sexually victimized. The establishment of PREA helps to ensure that prison staff treat these occurrences as such, that staff provide victims with the necessary treatment and care and that perpetrators are sanctioned or punished appropriately. Although there is a long history of attempting to change the criminal justice culture to make it free of sexual abuse and sexual harassment, the establishment of PREA has

increased the depth and reach of what was previously possible.

PRISON REFORM

Prison reform—in its narrowest sense—is the attempt to ameliorate conditions for those incarcerated (i.e., reform prison conditions), develop a

more effective and fair penal system, or implement alternatives to prison. Sometimes the term is used interchangeably with *criminal justice reform*, although the latter is more of an umbrella term that includes reform at the front end of the criminal justice system (law enforcement) and back end as well (reentry). Thus, prison reform is the attempt to address one of several parts of the criminal justice system.

Throughout history, religious groups, business leaders, philanthropists, scientists, scholars, advocates, activists, and elected and governmental officials have all become involved in prison reform. Early involvement often centered on the search for the cause of crime and rehabilitation of the offender. More recent times, however, have been marked by a more punitive response to crime as the sense that *nothing works* became popularized beginning in the 1970s. Since then, discourse around prison reform has become centered more on issues of public safety and fiscal responsibility than on concerns about human rights or rehabilitation of the offender.

This entry first describes the various types of prison reform. Then, it reviews the history of prison reform, primarily in the United States. The entry concludes with a discussion of present-day concerns surrounding prison reform.

Types of Reform

Prison reform can be divided into several distinct types of reforms. *Prison conditions reform* usually seeks to make prisons either less violent or less congested or aims to increase access to educational and treatment programs. *Sentencing reform* aims to address inequities in prison sentencing, the role of discretion in sentencing, and disproportionality between crime and sentence. A third type of prison reform involves the development and implementation of *alternatives* to prison, such as community-based treatment programs, community supervision, fines, or restitution.

Conditions

Prison conditions reform has been a focus of reformers since the beginning of prisons. With relatively few prisons in the late 18th and early 19th centuries, juveniles and adults were housed

together in prisons, and women were usually placed in quarters within these prisons with little, if any, gender separation. Despite rampant sexual abuse, most reformers paid little attention during this time to the unique vulnerabilities of women in prisons since they constituted such a small part of the overall prison population. Although attention has increased in modern years, sexual abuse by corrections staff still remains a widespread problem in prisons throughout the United States.

Interestingly, solitary confinement—today recognized by many scholars, psychologists, and human rights advocates as potentially harmful—was implemented in the earliest prisons as a more humane alternative to the deplorable congregate living conditions that previously existed in those facilities. Today, prison conditions reform is often sought through litigation by attorneys over issues such as access to mental health and substance abuse treatment services or the excessive use of solitary confinement. Excessively high phone rates, the quality and quantity of food services, and medical neglect are also common issues in prison conditions reform.

Sentencing

Sentencing reform has often reflected the public's attitude toward crime. Since the late 1960s, a series of sentencing reforms have taken a more punitive role than the long rehabilitative era that preceded it. Only recently have states begun taking measures to roll back some of the harsh measures instituted in previous decades. Some states are experimenting with decriminalization or legalization of small amounts of marijuana or the downgrading of charges from felony to misdemeanors. Some states also appear to be relieving their corrections population by granting parole to more prisoners. Other states are increasing the amount of *good time* that those in prison can earn for education and vocational programs.

Alternatives

Many U.S. states, experiencing both a budget crisis and a rapidly increasing prison population, have begun experimenting with alternatives to prison. Community-based treatment programs have garnered increased attention as states look to

cut their corrections costs. Addressing substance abuse or mental health issues in the community is much cheaper than doing so in prisons and is considered a more humane alternative to incarceration. Specialty courts, such as drug courts and mental health courts, have proliferated. As of 2018, there are over 3,000 drug courts and about 350 mental health courts in the United States. Other alternatives promoted by reformers include an increase in electronic monitoring and in the use of probation, fines, or restitution as alternatives to prison. Community service can also serve as a viable alternative for low-level offenses, but it is typically used only for minor offenses.

History of Prison Reform

From the late 18th century to the early 19th century, prisons were used only to hold an offender until a verdict was delivered, and a magistrate judge could mete out a punishment, the most common of which were whipping, branding, and maiming. Prison sentences as they are understood today—terms of imprisonment measured in months, days, or years—primarily did not exist in the early years of the United States. Early reformers such as John Howard in England and Thomas Eddy in New York spoke against these draconian corporal punishments of the time and supported incarceration as a punishment for those who had committed crimes so that they could be rehabilitated.

Several groups were established to address prison reform during the 18th and 19th centuries. In 1787, the Philadelphia Society for Alleviating the Miseries of Public Prisons formed to create more humanitarian conditions within prisons. The New York Prison Association also formed in 1844 to advocate against many of the harsh prison conditions of the time. Throughout the first half of the 19th century, crime was often viewed as a character flaw, and most reformers believed that properly run prisons could rehabilitate people of the sin of crime. This view shifted during the late 19th century, and by the 1890s, prison reform got swept up during the broader reform movement of the Age of Progressivism. The depression of the mid-1890s and the Great Depression beginning in 1929 shifted the views of people who began to believe that poverty must be prevented if crime is

to be prevented. This era marked a growing dependence on government intervention to fix societal ills combined with a shift in environmental explanations for crime that would last until the 1970s.

The 1970s brought in a new era of *tough on crime* measures. Many scholars attribute this change to a number of factors: the political radicalization of prisoners, an uprising at Attica over deplorable prison conditions, and the publications of two significant pieces of penal scholarship, *Evaluation of Penal Measures* by Leslie Wilkins in 1969 and Robert Martinson's 1974 summary of his upcoming book *The Effectiveness of Correctional Treatment*. Whatever factors caused the shift, *nothing works* became the mantra that would carry on for the next several decades in prison reform policy. Rehabilitation, which had guided prison reform ideals for almost two centuries, was dead.

Prison reform since the 1970s has mostly reflected this new mantra. The 1984 Sentencing Reform Act abolished federal parole, and the Violent Crime Control and Law Enforcement Act of 1994 created a variety of new crimes, expanded the death penalty, and eliminated Pell Grants for prisoners pursuing higher education. A collection of other harsh measures such as truth-in-sentencing laws, mandatory minimums, and habitual offender laws have spread throughout the nation and contributed to mass incarceration at unprecedented levels.

Since the turn of the 21st century, however, states have begun a series of steps to roll back many of these harsh measures instituted during this *tough on crime* era. Scholars, advocates, and politicians alike have embraced a new mantra: *smart on crime*. A number of prison reform bills have either been passed or introduced in Congress and various state governments. The Fair Sentencing Act of 2010 reduced the sentencing disparity between crack and powder cocaine from 100-1 to 18-1. The Smarter Sentencing Act (still in Congress as of 2018) appears likely to make it retroactive. Other proposals aim to reduce or eliminate mandatory minimum sentences and increase rehabilitative and educational program for those in prison who are deemed low risk of recidivism. Many of these proposals are incremental at best, and while none of them alone are likely to make sweeping

changes that will return the United States to pre-prison boom incarceration rates that the *tough on crime* era appears to be over bodes well for reformers hoping to return to a more rehabilitative era of prison reform.

Concerns Surrounding Prison Reform

Not everyone supports the more rehabilitative ideals of prison reform. Some people and groups representing victims of crimes and crime victims' families, for example, have remained steadfast in their opposition to proposals that aim to reduce the lengths of prison sentences. Others, however, agree that far too many people who commit crimes in the United States receive prison sentences disproportionate to their crimes, and the conditions by which they serve their time are unduly harsh. Even still, a huge gap in consensus exists among prison reform advocates, activists, scholars, and politicians about how best to address the myriad of issues related to prison reform.

One common criticism is that many of the most popular prison reforms proposed in the political arena either lack sustainability, are misguided, or will not provide the bold change proponents promise. In the interest of political palatability, politicians are often guilty of proposing incremental changes while promising bold action. Many reforms today focus almost exclusively on the *three nons*—nonviolent, nonsexual, nonserious charges. Research, however, has shown that more than half of the extra prisoners added since the 1980s were imprisoned for violent crimes. Reforms that do not address the sentencing structure of violent crimes—including retroactivity—are unlikely to reverse the trend in mass incarceration or create a lasting impact. Other scholars have pointed out the limitations of reforms that do not address the role discretion plays in increasing incarceration. Since the 1970s, though, key agents in the criminal justice system—particularly on the front end—have become increasingly punitive.

Sometimes attorneys, advocates, and scholars are at odds over how to best seek prison reform. A growing body of research shows how prison conditions litigation initiated by attorneys or advocacy groups out of concern for their incarcerated clients' well-being led to new prisons being built to improve prison conditions (e.g., ease overcrowding).

Finally, there are those who argue that prisons are an outdated form of punishment that have no place in a 21st-century society and prison reform proposals that aim to make prison sentences more equitable or make conditions less inhumane are misguided. Rather than working to improve the penal system, prison abolitionists argue that we should instead work to dismantle incarceration and rethink our historical approach of addressing crime after the fact with punitive measures. Furthermore, prison abolitionists point out that prisons are saturated with racism and sexual violence, and reforms that have attempted to ameliorate these conditions have often failed miserably. Community-based treatment programs are better equipped to address the multitude of social problems at the root of many crimes than are treatment programs implemented in artificial prison environments coercive by nature.

A growing number of scholars have challenged scholars and society to envision alternative ways of addressing crime rather than relying on prisons. Prison reformers and prison abolitionists have been able to find common ground with proposals that promote alternatives to incarceration. Time will tell whether they will be able to find common ground for addressing other problematic aspects of prisons as well.

PRISON SECURITY LEVELS

Prison security is a fundamental responsibility of any prison system. Prison security levels are set according to the severity of the crimes that the prisoners have committed, the risk the prisoners represent to the good order of the prison in which they are held, and the risk presented to the general public should the prisoners escape. Security in prisons is vital in order to maintain high standards of custody, care, and control. It is essential to minimize violent conflict, for example, assaults and prison riots, and to manage effective and purposeful regimes.

On a daily basis, security measures and practices determine the movements and activities of prisoners, for example, the times they are locked up and unlocked from their cells, and may be subject to cell and body searches. They also determine the quality of life in prisons. Prison security is integral to the degree of legitimacy inmates view the prison as having, the standards of care provided to vulnerable prisoners such as those who are mentally ill or at risk of self-inflicted death and self-harm, and staff–prisoner relationships.

This entry focuses on the different security levels and systems that have been implemented to ensure prisons are well ordered, safe, and secure, and also humane and purposeful, and in which human rights norms and standards of care, respect, and fairness are upheld.

Types of Prison Security

Prison security is commonly considered in terms of physical security, procedural security, and dynamic security. All three of these elements together are essential to the maintenance of good order in prisons and a safe and humane prison environment.

Physical security encompasses both outside and inside security and is primarily aimed at deterring and preventing escapes. This is achieved through the physical design and architecture of prisons: the perimeter wall; observation towers; cells, including designated areas of isolation and solitary confinement; gates and fences; and also surveillance and detection systems, for instance, cameras, X-ray machines, metal detectors, and alarms. Although not exclusive to them, physical security is normally associated with high-security facilities such as the so-called supermax prisons, which operate highly restrictive regimes characterized by extended periods of solitary confinement and limited human contact with staff and other prisoners.

Procedural security consists of measures and practices undertaken by staff to control everyday routines and regimens, including counting prisoners; deciding how, when, and where prisoners are allowed to move around prisons; the methods used for cell and body searches; and the maintenance and enforcement of disciplinary rules and regulations. Procedural security also involves contingency planning and being vigilant to potential security risks such as interprisoner violence. Separating prisoners using instruments of restraint and supervising prisoners in areas of isolation and solitary confinement are important procedural duties. Unlike physical security, which is static and consists of the physical infrastructure of prisons and the use of equipment and technology, procedural security requires high levels of interpersonal engagement and is dependent on the deployment of a sufficient number of competent and well-trained staff.

Similarly, *dynamic security* is dependent on high levels of staff–prisoner engagement. Considered to be an outcome of constructive and responsible relationships between prisoners and prison staff, dynamic security stems from staff having knowledge and understanding of the prisoner population.

An outcome of staff treating prisoners with dignity and respect is that prison environments are safe and peaceful and encourage higher levels of prisoner involvement in regime activities that aim to support their reintegration back into society.

Categories of Prison Security

It is typical for prison systems throughout the world to categorize prisoners according to the level of security they require. Prisons range from extremely high levels of physical security for prisoners assessed as presenting a serious risk of harm to *open prisons* that comprise much lower levels of physical security and allow prisoners' relative freedom of movement and the opportunity to work outside in the local community. In between are *closed prisons* that provide intermediary security categories and may function as training or resettlement prisons. Many prison systems are progressive in that prisoners may be reassessed and reallocated to different levels of security depending on their behavior in prison, incident history, and the length of their sentence. For example, many life-sentence prisoners are eligible for recategorization to progressively lower levels of security so they may prepare for their eventual release. Another example is adult male prisons in England and Wales that operate according to four security categories (Category A, Category B, Category C, and Category D), the first three of which correlate with the security categorization used in U.S. jurisdictions (maximum security, medium security, and minimum security).

Category A or maximum security prisons are for those whose escape would be highly dangerous to the public and national security. Such prisoners include prisoners convicted of murder, rape, firearms offenses, possessing or supplying explosives, importing or supplying Class A controlled drugs, and terrorism offenses. These prisoners are typically divided into standard risk, high risk, and exceptional risk.

Category B or medium security prisons are for those whose escape would present a serious risk but for whom the highest security measures are not necessary. This includes prisoners held on remand.

Category C or minimum security prisons are for those who cannot be trusted to open

conditions but who do not present a serious risk of escape.

Category D prisons are for those who are trusted not to escape and who have been assessed as being eligible for temporary release and home leave.

Women and children (12–17 years) and young people (18–21 years) are typically held in separate prisons with different security levels.

Political and Cultural Context of Prison Security

In all prison systems throughout the world, prison security levels are subject to political and cultural change. The institutional and operational frameworks, policies and procedures, staff instructions, and prison rules and orders that govern the way prison security is managed in a country at any one time are strongly influenced by its constitution and legal arrangements. Official reconsideration and reprioritization of prison security is also likely to be influenced by particular incidents and events in prisons and the official inquiries into them such as high-profile escapes, riots, and changes in the overall composition of the prison population. Such events may trigger anxiety and concern within the general public, which, according to some criminologists, has resulted in growing demands for tighter security and harsher regimes particularly in the United States and United Kingdom. Finally, levels of investment, the physical infrastructure, and the staffing resources made available to prison systems affect prison security. In some countries, physical security is prioritized over procedural and dynamic security to compensate for inadequate levels of investment and staff shortages. In others, prison staff have left control in prisons in the hands of violent prison gangs.

Today, a number of human rights instruments set out internationally recognized standards of imprisonment. These include the United Nations Standard Minimum Rules for the Treatment of Prisoners (the Nelson Mandela Rules, 2015) and the European Prison Rules (revised, 2006). Nevertheless, political and cultural variations remain in the security measures adopted in any particular country. To illustrate, it is instructive to consider how some of these political and cultural changes have played out since the 1960s in England and Wales.

Prison Security in England and Wales

Throughout the 1960s, political and public concern over security levels in prisons in England and Wales was prompted by a steady rise in the number of escapes from prison, most notably of three high-profile prisoners: two of the Great Train Robbers, Charlie Wilson in 1964 and Ronnie Biggs in 1965, and the spy George Blake in 1966. The subsequent Mountbatten Report, published in 1966, recommended the introduction of a new categorization system (see Categories of Prison Security section); an intensification of security measures throughout the prison system as a whole; and that the most difficult and high-risk prisoners be *concentrated* in one top security prison to be built on the Isle of Wight. With respect to this last recommendation, concerns over the difficulty of controlling such a prison and the likelihood of it becoming overly restrictive and repressive meant that the policy was never implemented. Instead, ever since, high-risk prisoners have been dispersed and held along with the mainstream population in a small number of category B prisons with upgraded security.

Throughout the 1970s and 1980s, the prison population continued to grow in England and Wales, rising from 39,820 prisoners in 1975 to 48,872 in 1988. A failure to build new prisons to accommodate the extra numbers resulted in severe overcrowding throughout the existing prison estate. For many commentators, this was the context for the Strangeways Prison riot of April 1990, which lasted for 25 days and triggered a series of copycat protests in other prisons throughout England, Wales, and Scotland. However, the subsequent inquiry into the causes of the riots, conducted by Lord Justice Woolf and published in 1991, cited the corrosive effects of severe overcrowding, unsanitary and squalid conditions, and repressive regimes, and called for prisons to be founded on the tripartite principles of *custody, care, and justice*. Any intention of the government of the day to pursue such a progressive agenda of penal reform was soon overtaken by the high-profile escapes of five Irish Republican Army prisoners from a Special Security Unit at Whitemoor Prison in 1994 and three life-sentence high-security prisoners from Parkhurst Prison in 1995.

As with the previous Mountbatten Report, the subsequent inquiries into the escapes resulted in increased levels of physical and procedural security, including improvements to perimeter walls, an increased use of technology, more frequent and thorough cell and body searches, the introduction of mandatory drug testing, and a reduction in home leave.

Since the 1990s, government reforms to the prison system in England and Wales have continued to prioritize physical and procedural security while also seeking to modernize prisons, diversify and extend provision between the public and private sectors, transform rehabilitation outcomes, and reduce costs. A report published in 2015 by the House of Commons Justice Committee criticized the pace of change, concluding that estate modernization and reconfiguration and a reduction in operational costs had resulted in a significant deterioration in safety. Specific challenges to security were identified as an increase in prisoner complaints regarding the imposition of restrictive regimes; staffing shortages and diminishing staff–prisoner relationships; an increase in the availability of drugs, including the so-called legal highs; and significant rises in the number of assaults and self-inflicted deaths in prisons.

Balancing Prison Security and Care

This account illustrates the tension often apparent in prison systems around the world between, on the one hand, ensuring prisoners are held securely and, on the other, that a duty of care is in place to ensure prisoners are treated fairly, with humanity, dignity, and respect. The two core objectives of imprisonment are interdependent. The degree to which security is compatible with care influences whether prisoners acknowledge the legitimacy of their incarceration and the authority of prison staff to maintain governance and control over them. Some prison authorities have attempted to balance physical, procedural, and dynamic approaches to security. For example, since 2004, Her Majesty's Prison Service in England and Wales has put into operation the so-called decency agenda that has affirmed the importance of good staff–prisoner relationships, treating prisoners

with respect and dignity, and making available adequate resources and purposeful activities to promote their resettlement after release. In the United States, for example, prisons known as *direct supervision jails* have been developed to balance physical security alongside an active management strategy to reduce problem inmate behavior based specifically on principles of dynamic security. Yet the danger that security considerations will prevail over all else and be implemented illegally, unnecessarily, and disproportionately, thus increasing the risk of disorder in prisons, is a constant one. For penal reform organizations, human rights lawyers, independent monitoring boards, trades unions, government committees of inquiry, prison officials and prisoners alike, and the overuse of physical security—increasingly in the form of surveillance and solitary confinement—remain pressing problems to contend with.

PRISONS

In the United States, prisons are state or federal institutions designed to house individuals convicted of felony crimes. Prisons are governed through criminal justice systems, and in most countries, prisons are used to house people who have been sentenced by the criminal courts. This entry briefly explores the history of imprisonment and then proceeds to ask questions regarding what prisons are for, who is sent to prison, and what happens to people when they are imprisoned.

History

This history of the prison can be traced back to at least 1700 BCE and the *Code of Hammurabi, Babylon*. Ancient Egyptians used imprisonment as a means of detention, and prisons were also widely used in Ancient Greece, although primarily to house debtors. Imprisonment, in the form of penal servitude in metal and salt mines (*ad metalla*) or chain gangs (*opus publicum*), was the primary punishment in the Roman Empire. Indeed, for Johan Thorsten Sellin, author of *Slavery and the Penal System* (1976), the history of imprisonment is intimately connected with that of servitude and slavery.

In England in 1166, King Henry II issued the Assize of Clarendon, which ordered his sheriffs to build a jail in each county. Jails held debtors and felons awaiting trial. In 1556, the first House of Correction was established at Bridewell, and in 1609, King James I made the House of Correction (popularly referred to as *Bridewells*) obligatory in every English county. Prisons at this time in England and across Europe were largely, but not exclusively, used as forms of detention for people awaiting punishment. The death penalty, public forms of corporal punishment (e.g., public whippings), banishment, and transportation were the main state punishments from the 16th to the 18th centuries. However, by the end of the 18th century, popular anguish about public execution, *torture*, and slavery raised serious moral questions about such practices. From the 16th to the 19th centuries, Western societies were rapidly changing from a political economy of feudalism to first one of mercantilist capitalism and later one of

industrialized capitalism grounded in the exploitation and domination of wage laborers in both the home nations and their colonies. As noted by penologists George Rusche and Otto Kirchheimer, practices of punishment, and especially imprisonment, reflected such socioeconomic changes.

By the early 1800s, across virtually the whole of the globe, the prison was considered a place *for* punishment. At this time, there was a change in emphasis from the elimination to the reclamation of the offender and the belief that new reformed prisons could act as a technology of salvation. Two diametrically opposed philosophies underscored this transformation: Christianity and Utilitarianism. On one hand, Christian reformers believed that the immorality of *crime* could be rectified by manipulating the offender through isolation in a prison cell where the offender could reflect and repent of his or her unrighteousness. Utilitarian philosophers, on the other hand, pleaded for the universality of reason and for acceptance of the idea that reformation could only take place through the socialization of the offender's proclivity for pleasure. This would be achieved by constant inspection. The approaches to *reformed prisons* in the United States, France, and England at this time created the template for the modern prison.

In the United States, Pennsylvania led the way, passing new laws in the 1780s for the penal servitude of offenders through public works. In the 1790s, Walnut Street Prison opened in Philadelphia. This approach was based on silence and separation through solitary confinement and became known as the *separate system*. An alternative approach, known as the *silent system*, which allowed prisoners to work together in silence, was implemented at Auburn State Prison in New York in the 1820s. The influence of these prisons was felt across the Atlantic. In England, in 1810, the Holford Committee recommended that a convict prison should be built at Millbank, on the River Thames in London. The General Penitentiary was designed to hold 1,000 prisoners and later led to the opening in 1842 of Her Majesty's Prison Pentonville. Pentonville housed 520 prisoners in separate cells and became the model prison in the Victorian era. Its regime—based on solitude, hard labor, religious indoctrination, and surveillance—became the basis for reformed prisons in England and many other places.

What Are Prisons For?

Since the 19th century, prisons have been justified on a number of different grounds. Retributivists argue that prisons should be places of pain because the prisoner, through his or her criminal offense, deserves to suffer. This justification has problems because it is based on the assumption that imprisonment can deliver justice in unequal societies and that two wrongs can make a right. Another justification is that harsh penal regimes, penal servitude, and discipline can act as deterrents to both individual offenders and the general public more broadly. This is closely connected to the doctrine of *less eligibility*—the belief that the conditions of imprisonment must not be higher than the living conditions of the poorest laborer. According to Rusche and Kirchheimer in 2003, less eligibility has been the “leitmotiv of all prison administration down to the present time” (p. 94). The problem with deterrence is that it can never be morally right to imprison one person for the benefit of others (general deterrence) and that there is no evidence that ex-prisoners reduce offending as a direct result of their imprisonment (individual deterrence). Prisons are also justified on the grounds of incapacitation and promoting public safety. Incapacitation, however, has an Achilles’ heel. Rather than preventing crimes, they are merely deferred; so when offenders are released, they may reengage in criminal behavior.

Perhaps the most influential justification for prisons is the claim that prisons can reform or rehabilitate offenders. The terms *reform* and *rehabilitation*, although often used interchangeably, in fact mean very different things. Reform ultimately means to change the offender. The aim of reformatory punishment is to alter the individual by attempting to reeducate, teach, train, or instill a new morality. The offender is in need of moral education—work, religion, schooling, or vocational training. Rehabilitation aims to restore the individual to the person he or she was before the crime was committed. This suggests that treatment is most important, and, just like medicine, if the problems could be correctly diagnosed, then the offender and ultimately society can be cured of problematic behavior.

Who Is Sent to Prison?

The *World Prison Population List* details prison population rates per 100,000 of the national population in 223 countries. In October 2015, there were more than 10.35 million people held in penal institutions throughout the world. More than half were held in just five countries: the United States (2.2 million), China (1.65 million), Russia (0.64 million), Brazil (0.61 million), and India (0.42 million). The United States has one of the world’s highest prison population rate at 698 per 100,000 of the general population (behind only the Seychelles). Prison populations have been growing rapidly across the world since the early 1970s. According to Nigel South and Robert Weiss, this can be explained by the rise of neoconservative governance and neoliberal political economy in the global North and the growing reach of neoliberal capitalism across the world, including in the global South, following the end of the Cold War.

The people who are in prisons often come from impoverished social backgrounds and are often people of color or indigenous populations in countries that are former colonies. In Australia, for example, people of aboriginal descent make up about 2% of the overall population but over 20% of the prison population. About half of the U.S. prison population is made up of African Americans, though constituting only 13% of the general population. The vast majority of prisoners are men. One in three young Black men are currently in prison, on parole, or on probation. Black American men are 8 times more likely to be imprisoned than White Americans, and if current trends continue, 29% of Black American men born today will end up in prison during their lifetime. Across Europe, there are disproportionately large numbers of foreign nationals in prisons, even in countries with relatively low prison populations. In 2013, David Scott reported that 32% of prisoners in the Netherlands, 23% of prisoners in Germany, and 33% of prisoners in Norway are foreign nationals.

Prisoners around the world are also people with complex and multiple needs. Many prisoners have grown up in care homes or have had significant family difficulties. Many are unemployed or receiving benefits before prison or do not have paid employment to go to upon release. In

addition, many prisoners are likely to be homeless or not living in a permanent accommodation prior to imprisonment. Many have no or only limited education (and often cannot read or write) and are in poor health, for example, with mental health problems, long-standing illnesses or disabilities, or substance usage problems.

It is also commonly accepted that offenders think and behave differently than nonoffenders. For example, offenders at moderate to high risk of crime engage in criminal thinking or have attitudes that are more antisocial than nonoffenders. Offenders are also more likely to associate with other offenders and less likely to engage in prosocial activities such as work or school, and prosocial leisure or recreational activities.

What Happens to People in Prison?

Prisons are a specifically designated spatial order controlling human freedom, autonomy, choices, actions, and relationships. External physical barricades regulate the conditions of social existence through sealing prisoners from their previous life, while internal control mechanisms survey constraints on the minutiae of the prison day. Security restrictions on prisoner movements—such as access to educational and treatment programs, religious instruction, work and leisure provision—are carefully structured and regimented around predetermined orderings of time and space. The architecture of the prison place determines the location of events and distribution of bodies and in doing so also highly regulates relationships.

According to Diana Medlicott, in one way or another, a sense of loss affects all prisoners. At times, prisons are places of frantic activities, highly structured routines, timetables, and regimentation. Paradoxically, at other times they are empty, dull, and motionless, where nothing is happening, but all the same, is passing at a fast rate. Scott and Helen Codd note that for some, the loss of freedom and time to live one's life, the enforced passivity, and the emptiness of time can be exceptionally painful. For others, prison creates an opportunity for change, to rid oneself of prior antisocial proclivities in favor of a new goals and prosocial agenda, thus avoiding a return to the prison environment.

PRIVATIZATION OF PRISONS

Prison privatization or *contract management* refers to the contracting of private companies by the state to provide custodial corrections. Proponents of contract management highlight increased efficiency and effectiveness and opportunities for innovation as primary advantages, but others contend that these benefits must be balanced by governments securing suitable contracts and ensuring that the state maintains responsibility for the allocation of punishment and prisoner duty of care. The following explores the various forms of privatization and discusses the catalysts to its emergence in modern times. After summarizing research around success, it outlines important issues in the future of prison privatization.

Background

Privatization of corrective services exists across all facets of custodial corrections, including prisons, juvenile detention, and immigration detention. The extent of private involvement in the corrections system varies. In some cases, private contractors provide services only, including food, health

care, or programs for education or rehabilitation, such as the French *prisons semi-privees*, in which noncustodial services are privately provided. At the other end of the spectrum are Design Construct Finance and Manage contracts, whereby private companies build and operate a new prison for a period of time, according to the contractual requirements of the state. Most often, privatization exists in a model described as contract management, with the private sector responsible for the operations of a prison that will ultimately be government owned. In this way, the state retains responsibility for *allocation* of punishment, while the private sector merely participates in *administering* aspects of the prison system on behalf of the government.

History of Privatization

In the modern era, privatization is a controversial and much-debated topic. However, the intersection of corrections and profit is not a new phenomenon. In Ancient Greece, rights in regard to private property were enforced by society, with the private sector providing punishment. Across Europe during the 17th century, families with an unruly relative could petition for imprisonment, with a fee paid to the prison administrator for the duration. Such enterprises became so popular that many private citizens opened their homes to lodge those considered an embarrassment to their families due to misbehavior or insanity, and private institutions, such as the *beterhuizen* of the Netherlands, flourished. Jailors in 18th-century prisons procured their income from the prisoners who paid for food and bedding, as well as through commercial activities within the prison, such as the sale of alcohol. Custodial privatization featured strongly in the history of Australian corrections: In 1788, the British government contracted ships for the transportation of convicts, and later, the supply of convict labor to free settlers. Similar leasing of prisoners for labor was seen in the United States following the Civil War, with the lack of state involvement and maximization of profits resulting in breaches of basic prisoner rights.

The move to recent privatization commenced when Corrections Corporation of America won a contract to own and operate a Houston (TX)

immigration detention center in 1984. After this, privately operated prisons spread quite rapidly across the United States and later emerged in Australia (Borallon Prison, 1990), the United Kingdom (The Wolds, England, 1992; HMP Kilmarnock, Scotland, 1999), New Zealand (Auckland Central Remand Prison, 2000), and South Africa (Manguang Prison, 2001). In 2016, 12 countries worldwide featured prisons contracted to private companies in some form, with prisoner populations therein varying from 4% of the total prison population in South Africa to 19% in Australia.

Catalysts of Privatization

Arguably, the greatest influence on the emergence of prison privatization was the increase in prison populations globally, largely due to sentencing changes in the late 1980s. For example, as documented by Rynne and Harding in 2016, between 1990 and 2013, prisoner numbers increased by 86.5% in England and Scotland, 92% in the United States, and 115% in Australia. A consequence of this rapid increase was overcrowding of prisons, with existing infrastructure unable to meet the demand for safe and secure housing of prisoners. Furthermore, the physical conditions of some existing prisons, often built in the previous century, were such that the need for new facilities was dire.

Overcrowded prisons meant not only cramped living conditions but also limited access to education, training, and programs to address recidivism. Contemporaneous with overcrowded prisons was a decline in the physical and mental health of inmates and increases in behaviors such as violence, self-harming, and attempted suicides. In the United States, issues such as lack of access to adequate medical treatment and threat to physical safety led to legal decisions compelling prison systems to provide adequate medical and mental health care.

The surge in prisoner numbers across the globe occurred during a political period characterized by economic rationalization (reorganization to increase efficiency and decrease costs), free market ideology, and the belief that the public sector could be made more efficient through inclusion of private enterprise. Governments, seeking alternatives to pledging taxpayer dollars to fund building of new

amenities, were won over by the prospect of spreading payments across the lifetime of a contract, particularly given the speed at which private-sector construction advanced. Once built, ongoing costs associated with management and operations were expected to be lesser in privately operated facilities, with some U.S. states mandating minimum cost savings as part of awarded contracts.

While economic arguments may have been the strongest catalysts of privatization emergence, proponents also argued that prison regimes would benefit from involvement of the private sector. The move to privatization was envisaged by some as an opportunity to reform prison organizational culture and challenge long-standing norms, entrenched work cultures, and an existing emphasis on retributive punishment. Changes to staffing strategies due to greater flexibility around pay and conditions, technological advances, and innovative management techniques and service delivery strategies were theorized to have financial benefits and improve service delivery. Where private institutions do show improvements in quality, there is a cross-fertilization effect for the public prison system, which must compete with the success of the private sector, thereby stimulating enhancement sector wide.

Privatization Success

Despite a wealth of research, determining the economic success of privatization is difficult due to methodological issues around comparisons between publicly and privately operated institutions. Cost-effectiveness studies are affected by issues such as when institutions were built, with many publicly operated prisons being more costly due to aged facilities. Furthermore, factors such as prison security levels, as well as variables related to the prisoner population (e.g., age, gender, health), must be controlled to obtain useful findings. These issues aside, cross-sector cost comparisons suggest that savings can be substantial, particularly when reductions attributed to lower infrastructure costs are acknowledged. A 2013 study, which included staffing costs as well as those related to other financial factors, suggested that privately operated prisons could reduce overall costs by between 12% and 58%. Similarly, in the United Kingdom, the Home Office concluded

that, all factors considered, private-sector prisons produced a saving of around 12.5% during a 4-year period, although savings were seen to decline over time.

The effectiveness of privatization in reforming prison quality can be assessed according to observed differences in organizational culture (collective assumptions, values, and beliefs that shape staff attitudes and behaviors), social climate (perceptions of the organization and its operation), and service delivery (success of day-to-day operations). Studies examining prison quality are mostly restricted to those conducted within the United States, the United Kingdom, and Australia. In general, research indicates that public prisons outperform private prisons on security and order measures, with some reports showing lower rates of safety incidents and injuries to both inmates and staff in public institutions. Private prisons perform best in terms of quality of life for prisoners, although this may be partly explained by newer facilities. All things considered, prison quality differs between the public and private sectors; however, the extent and type of difference is influenced by institutional differences rather than differences according to sector alone.

For example, U.S. research on prison quality found minimal difference between public and private facilities, particularly when considering prisoner perceptions. However, when Charles Logan compared the New Mexico Women's Correction Facility (managed by Core Civic, formerly Corrections Corporation of America) to government institutions in 1992, he concluded that the privately owned/operated prison performed better on six of eight factors investigated, suggesting better service delivery. Australia's privately operated Junee Prison was assessed by the NSW Department of Corrective Services yearly from 1994, with results suggesting that the Junee Prison prisoner management model exceeded that of the public system, particularly when considering officer-prisoner interaction and case management. While in some areas Junee did not perform as well as the public comparisons (e.g., offenses in custody and assaults on officers), positive organizational culture was observed for all 4 years of the study, and staff retention rates remained high, suggesting this culture had become entrenched in the

organization. Reviews of Western Australia's Acacia Prison by an autonomous prison's inspectorate established in 2000 concluded that while Acacia's peak performance was in the years after it opened, it continued to operate at good standards such as those achieved by comparable public institutions.

Research from the United Kingdom showed that the most effective privately built and operated institutions outperformed comparable public prisons; however, some poorer performing private prisons were among the worst performers of all prisons reviewed. Prisons found to perform well in terms of programs and work opportunities tended to perform poorly in terms of safety and security, regardless of which sector they represented, suggesting that variations in effectiveness did not appear to be determined according to whether operation was public or private but due to differences in quality between institutions.

The ability of a prison to influence reductions in recidivism is an important measure of prison effectiveness. There are also difficulties in drawing strong conclusions from recidivism research, due to methodological issues such as failing to consider prison transfers. For example, UK research based on Ministry of Justice data proposed that private institutions decrease recidivism by as much as 10%; however, these findings were based on comparisons of raw data and did not consider any interprison variables. Overall, similar to findings around economic benefits, research investigating recidivism suggests that private institutions may initially perform better than public comparisons, but over time this effect weakens and in some cases reverses.

While privatization might offer economic advantages, better facilities, and the opportunity for improved prison culture, potential negatives of involvement of private industry in correctional practices exist. When prisons operate as businesses, profits can be boosted through such cost-cutting measures as employing fewer staff, reducing officer training, and limiting access for prisoners to medical and psychiatric professionals. Furthermore, profits are inextricably tied to increases in prison populations and sentence lengths. Lobbying, and support for private prison contracts by government employees, raises questions around ethical challenges and the potential for corruption in an environment that sees transitions of personnel from

influential governmental positions to employment within the private prison sector.

Privatization Into the Future

With governments under increasing pressure to provide citizens with the services they demand at minimum costs, it is likely that areas such as corrections will continue to look to private sector involvement into the future. Regardless of the extent of private sector involvement—whether delivery of noncustodial services only or direct management—there are some issues around privatization that warrant consideration.

It is essential that the division between the duties of the state and the operations of private corrections companies be enforced, with the state maintaining legal responsibility for ensuring duty of care for prisoners. Central to achieving this is ensuring that contracts are clear and specific rather than generic in detail, with a contract period of reasonable length (e.g., 5 years with options to extend). Performance should meet clearly specified requirements at appropriate intervals. Specificity in contracts, however, must be balanced so as not to quash the innovation that privatization was argued to introduce.

Given that those contracted to provide corrections services are often large, global, general service companies, ensuring adequate knowledge of the local situation and ability to operate according to these demands is also essential. While profits may be available in some areas of corrections, company reputation can be damaged when service provision does not meet expected standards.

PROBATION

Probation is a disposition within the criminal justice system whereby an offender serves a term of supervision in the community under the authority of a probation agency. Probation is typically served in lieu of sentence to jail or prison. Unlike parole, probation is generally a sentence unto itself rather than a period of supervision completed after a prison term and is often conceptualized as a type of diversion from incarceration.

Probation is the most common criminal disposition in many nations, including the United States and Canada; for example, as of 2015, 3.8 million of the approximately 7 million adults in the U.S. criminal justice system were on probation. Although probation has been used informally in the United States for more than 150 years, it has undergone substantial philosophical changes over the past few decades.

This entry provides a brief history of probation and discusses the overarching philosophies, practices, and innovations in probation. The primary focus of this entry is adult probation in the United States, but some discussion of probation in other contexts is provided. The entry concludes with a discussion of the future of probation.

Historical Roots of Probation

Probation in the United States is generally traced back to the practices of John Augustus (1785–1859), a Boston business owner and member of the Washington Total Abstinence Society. The society, in addition to promoting abstinence from alcohol, advocated for the kind treatment of people with alcohol problems. Augustus sought to extend kindness toward first-time offenders at the

local courthouse, where he paid bail for men struggling with alcohol abuse whom he deemed good candidates for rehabilitation. Augustus rehabilitated his first offender in 1841, and over the next several years, he rehabilitated nearly 2,000 people. Augustus was quite successful in his efforts—it is reported that only 10 of the men he rehabilitated had further entanglement with the criminal justice system. Around the same time, Matthew Davenport Hill (1792–1872) was working toward a similar goal in England, though his focus was juvenile offenders. Hill is viewed as the originator of probation in England.

In the United States, Massachusetts legally formalized probation in 1878, and a handful of other states followed suit in the late 1800s. Probation proliferated across the states in the early 1900s, and federal probation was created in 1925. As of 2017, all 50 states have formal probation. In the United States, probation is most often operated at the state level, though in a minority of states probation is run at the county level. In countries such as Canada and England, there is a national body overseeing probation, but the operation of probation is carried out by province- or county-level agencies. Although parole is different from probation in that it is typically reserved for offenders reentering society after a prison term, probation and parole are run within the same agency in many states. Furthermore, although adolescent offenders are typically processed in the juvenile justice system (separately from adults), in many U.S. states, the juvenile and adult systems are overseen by the same agency.

The dominant philosophy in U.S. probation agencies throughout most of the 20th century echoed the rehabilitative goals of Augustus. Probation officers functioned much like social workers and worked to change the criminal behavior of their clients using a therapeutic, human services approach. However, the philosophy of probation shifted multiple times since 1970. From the decade between 1971 and 1980, probation followed a brokerage model, whereby probation officers moved away from direct service provision to their clients toward facilitation of referrals and services within community-based social services agencies. Political changes brought about an about-face in the last two decades of the 20th century. Given public perceptions that probation was too soft on

offenders, agencies moved toward a heavier use of sanctions and punishments. Since the beginning of the 21st century, probation has shifted its focus on rehabilitation and use of practices supported by research evidence, as described in the following section.

Current Practices and Innovations in Probation

The primary objectives in contemporary probation practice are the assessment and supervision of probationers. Many probation agencies conduct presentence investigation reports, whereby a probation officer gathers information on the offender and his or her current offense to aid the court in making decisions regarding appropriate sentencing and placement into community programming aimed at rehabilitating the offender. Assessment can also inform the type and intensity of programming once the offender is assigned to probation. Many well-validated risk assessment tools exist to help agencies measure each offender's risk of recidivism—the likelihood that the offender will commit a new crime or otherwise do poorly on community supervision.

The other primary function of probation agencies is supervision of probationers while they complete their probation term. Probationers are generally assigned to a probation officer's caseload, and the officer becomes responsible for monitoring the probationer's compliance with the terms of probation. In addition to abiding by all state and local laws, probationers are required to meet the conditions of their probation supervision to successfully complete their supervision term. Standard conditions of probation vary by jurisdiction but typically include maintaining adequate employment or attending school full-time, paying restitution or fines, avoiding drug use and excessive alcohol use, and maintaining an appropriate residence. Probationers may also have a curfew and be unable to travel outside their home jurisdiction without prior permission from their probation officer. In addition, probationers who are judged to be in need of substance abuse or mental health treatment may be mandated to attend such treatment as a requirement of probation. Probation officers monitor probationers' compliance with these probation terms and respond to

violations with verbal or written warnings; persistent or serious violations may lead to the probation officer filing a violation report with the court whereby the judge may temporarily or permanently revoke probation, which can result in incarceration.

As probation in the United States has moved toward a rehabilitative approach, there has been increased attention paid to probation practices that have research supporting their effectiveness in decreasing the rate of reoffense and technical violations for probationers. The most widely supported model of correctional supervision is known as the Risk-Need-Responsivity (RNR) model. The RNR model was developed by Donald Andrews and James Bonta and provides a set of principles to guide offender rehabilitation. The risk principle specifies that agencies should measure the recidivism risk of every offender entering their agency, preferably with the use of a structured risk assessment tool, and this risk information should be used to inform the intensity of programming for offenders. Specifically, high-risk offenders should receive the most intensive programming and more frequent supervision, whereas lower risk offenders should receive only minimal programming. The need principle directs agencies to identify criminogenic needs—changeable risk factors that can reduce an offender's risk of recidivism when successfully addressed in treatment. For example, substance abuse is a criminogenic need because substance abuse increases the likelihood that a probationer will continue to offend. If substance abuse is successfully treated, the probationer will be at a lower risk of reoffending. Finally, the responsivity principle provides guidance on how to implement programming with offenders in two ways. General responsivity prescribes the use of psychological methods that are known to affect behavior change, such as cognitive behavioral techniques. Specific responsivity calls for the consideration of the individual needs of an offender in correctional programming. For example, probation officers should attend to the motivation level of an offender when working with him or her. The RNR model also directs agencies to use core correctional practices, a set of principles guiding how probation officers interact with the offenders they supervise; officers should build high-quality relationships with offenders and use a skill-building

approach in supervision. Effective use of RNR and core correctional practices can dramatically increase the likelihood that probationers can remain crime free.

It is important to note that RNR is a set of principles, not a program. However, many programs have been designed for use in probation agencies built around the principles of RNR. For example, the University of Cincinnati Corrections Institute developed a structured training program for probation agencies called *Effective Practices in Community Supervision* that has been shown to increase officers' use of core correctional practices during supervision with their supervisees. Another program with substantial research support is the Strategic Training Initiative in Community Supervision that was developed by the Corrections Research Division of Public Safety Canada. Researchers continue to seek innovative ways to improve the implementation of these programs; for example, few studies have examined the use of coaches—specially trained probation officers who review supervision meetings conducted by their colleagues and provide feedback on the use of core correctional practices—with promising results.

A number of innovations have emerged in probation agencies to meet the unique needs of specific subgroups of offenders. For example, gender-specific programming has emerged to meet the unique needs of female offenders, who often have extensive histories of abuse and substantial mental health needs. Gender-specific programs integrate treatment for post-traumatic stress into probation supervision. Specialty caseloads have been developed in many agencies, whereby a probation officer with specialized training supervises a caseload composed of a specific subtype of offenders. Many varieties of specialty caseloads have been developed, some based on specific types of offenses (e.g., domestic violence, driving while intoxicated) and others based on specific types of offenders (e.g., offenders with mental illness, military veterans). Notably, the specific features of these caseloads may be unique to the agency where they are housed, and although some of these programs have demonstrated promising results, more research is needed to fully understand whether and how these caseloads work to reduce recidivism. Other innovations include

police–probation partnerships, whereby police officers work with the probation agency to deter crime and enforce curfews, and neighborhood-based supervision, whereby probation officers are assigned to offenders in specific neighborhoods and spend time in the community.

The Future of Probation

Probation is likely to remain a widely used criminal justice disposition in the United States and elsewhere given its cost-effectiveness. Depending on the jurisdiction and intensity, probation in the United States costs between US\$5 and US\$10 per day per offender, compared with the US\$75 per day or more it costs to incarcerate the same offender. Faced with budget crises, many states in the United States have sought to downsize their prison populations through changes in sentencing guidelines and more widespread support of rehabilitation programs. Given that probation can produce meaningful changes in offenders' behavior for substantially less money, it is likely that it will remain the primary mechanism for supervising offenders.

Although the face of probation can be difficult to predict given the influence of public opinion and changes in the political climate, it is reasonable to predict that probation will continue to develop toward more of a casework model than a punitive one. Decades of research conclude that rehabilitative approaches consistent with RNR in probation yield improvements to public safety as well as cost savings, whereas punishment-based approaches can backfire and increase recidivism. As the field continues to innovate, it is likely that additional advances will be made in agencies' abilities to reap these benefits through improvements in staff training and implementation efforts.

PROBATION, SPECIALIZED

Specialized probation is a community supervision intervention that works with individuals in the criminal justice system who have a mental health diagnosis. Unlike standard probation programs, specialized probation is uniquely designed to address the complex mental health and criminogenic needs of individuals with mental illnesses. With their specially trained probation officers, small caseloads, and overall therapeutic approach to probation programming, specialized probation units aim to provide offenders with serious mental illness (SMI) with the support and services they need to desist from crime and address their mental health needs. This entry provides a brief history on the need for and development of specialized probation programs, describes their structure and purpose, and provides an overview of their challenges and level of effectiveness.

The Need for Specialized Probation Programs: A Historical Perspective

In the United States, for many years, the use of asylums or psychiatric institutions was not merely

a common practice but the singular option in working with people with mental illnesses. Prior to the 20th century, mental illness was a little-understood phenomenon, and individuals who presented with psychiatric symptoms were typically removed from their community and placed in isolated institutions. Over time, as knowledge of mental illness increased and the inability of psychiatric institutions to sufficiently respond to the complex needs of individuals with mental illness became apparent, the approach to treatment changed.

In the late 1960s and early 1970s, there was a national push to end the era of large, government-run mental health institutions and move toward a more community-based model. The hope was that by returning individuals with SMI to their communities to live and receive services, it would help to destigmatize mental illnesses and provide the individual with a healthier, more realistic rehabilitative environment.

While this process of deinstitutionalization was well intentioned, the structural support for this endeavor was not present in communities. Community-based services in the realms of supportive housing and mental health were not plentiful enough to support the influx of individuals with pressing mental health needs. This shortage of critical services created a void that came to be filled largely by the criminal justice system. This process is referred to as *transinstitutionalization* (i.e., the movement of individuals from one institution to another). The criminal justice system became a catchall, with police officers acting as first responders intervening in situations involving individuals with SMI. Jails and other detention facilities were often viewed as temporary housing for this vulnerable population and a means through which the system could deliver short-term services. Over time, individuals with SMI came to represent a disproportionate amount of the population involved in the criminal justice system, but the system was ill-equipped to meet this population's needs.

The Start of Specialty Probation Programs

Starting in the late 1980s, the criminal justice system began implementing interventions specifically for people with SMI. The initial wave of

interventions focused on the front end of the criminal justice system (i.e., police departments, courts, and jails) and was designed to divert people with SMI from traditional legal processing to the mental health system. Some of these front-end tactics included changes to prebooking strategies, new law enforcement training methods, and an increased focus on connecting offenders with SMI to community-based treatment programs. These approaches successfully diverted some people with SMI away from the criminal justice system, especially those with low-level criminal behavior, but a significant number still entered the jails and court system. In response, specialized court-based interventions, including mental health courts and specialized probation, began to take shape.

Specialized probation programs, along with most other specialized criminal justice interventions for people with SMI, began with a primary assumption that people with SMI were becoming involved in the criminal justice system primarily because of their mental health diagnoses and corresponding symptoms. This view, the *criminalization hypothesis*, suggests that mental health treatment is the primary means to reducing criminal justice involvement for people with SMI. As a result, the first generation of specialized criminal justice interventions for people with SMI, including specialized probation, focused on mental health treatment linkage as opposed to typical criminal justice processing.

However, over the evolution of these programs, a more nuanced understanding of the relationship between criminal activity and mental illness is taking shape. It is becoming more widely recognized, by scholars and practitioners alike, that only addressing the mental health needs of this population is a one-sided and limited approach. It is becoming clear that this presumption ignores the larger context of the individual and the fact that many offenders with SMI are subject to the same criminogenic risk factors as offenders without SMI, including criminal thinking, antisocial peers, and lack of educational and employment opportunities. In response to this growing awareness, the first generation of criminal justice interventions for people with SMI is beginning to adopt strategies to address these criminal risks, which will likely improve their effectiveness.

Description of Specialized Probation Units

Specialized probation programs are uniquely designed to better address the complex mental health and criminogenic needs of individuals with mental illness. In order to be eligible for these probation programs, an individual must meet the diagnostic criteria for a major mental illness. The range of accepted diagnoses can vary depending on the program, but often included are diagnoses associated with SMI, such as schizophrenia, bipolar disorder, and major depression.

Specialized probation programs intentionally differ from standard probation programs in several important ways. First, probation officers within specialized probation units typically have lower caseloads than standard probation officers. This reduced caseload allows officers to spend more time with their clients, aiding the probationers in their navigation of the program's varied mandates. Second, specialized probation officers receive sustained training on mental health issues and behavioral health problem management. This additional training gives specialized probation officers the tools to work effectively with offenders with mental illness and trains them to think more broadly about their clients' behaviors, struggles, and successes. The final core component of specialized probation is its active integration of community resources. Specialized probation officers work closely with community partners who provide direct treatment services to their clients. This collaborative relationship is meant to create a unified team that is acutely aware of a probationer's progress throughout the duration of his or her supervision. This team approach has the potential to create a highly supportive, encouraging environment for the probationer, which can significantly contribute to his or her success and overall experience on probation.

Challenges Posed by Specialized Probation

Probationers on both standard probation and specialized probation are expected to juggle a number of requirements in order to successfully complete their sentence, but these tasks can be tremendously more difficult to navigate for probationers

with SMI. Probationers with SMI often fail to adhere to the conditions of their community supervision for a variety of reasons. Perhaps one of the principal reasons is that offenders with SMI are at an increased risk of having a comorbid substance use disorder. On the probation officers' end, a dual diagnosis complicates the coordination of mental health treatment and necessitates integrated but often inaccessible substance abuse and psychiatric services. On the probationers' end, meeting the mandates of their probation program and avoiding infractions, while working to maintain their sobriety and mental health, is a difficult task. As these programs continue to evolve, it is becoming clear that the complex relationship between probation officer and probationer with SMI is a critical component to specialized probation's potential effectiveness.

Probation programs of all types are tasked with balancing public safety and rehabilitation concerns, and this dual responsibility carries over to each individual probation officer. The role of probation officer is inherently a dichotomous one: He or she is simultaneously expected to enforce compliance with probation conditions in order to protect public safety and to provide direct and supportive services in order to achieve individual rehabilitation. The complexities and varied responsibilities of the probation officer role are even more significant when supervising probationers with SMI, which supports the unique design of specialized probation programs (i.e., their increased training of officers and reduced caseloads). Because of the complexities that arise with probationers with SMI, specialized probation officers utilize problem-solving strategies and therapeutic approaches to address treatment non-compliance and other violations of probation mandates. While punitive measures can still be taken, the overall approach to noncompliance within specialized probation is to be more therapeutic than disciplinary. Within specialized probation units, the rehabilitative aim is equally as important as the aim of public safety.

Effectiveness of Specialty Probation

There is limited research on specialized probation for persons with SMI. Of the studies that have been conducted, the findings generally support the

effectiveness of the specialized mental health caseload. There is preliminary evidence in the areas of increased treatment engagement and improved mental health outcomes as well as potential reductions in recidivism. While more empirical evidence needs to be generated on this topic, specialized probation holds promise when it comes to producing positive mental health and criminal justice outcomes for probationers with SMI. The extent to which specialized probation programs address both mental health and criminogenic needs is critical to the shared desired outcomes of improved mental health and reduced criminal justice involvement. Through the accumulation of more rigorously tested evidence, national standards for specialized probation programs can be developed to create uniformity in program operations and implementation.

PROSECUTORIAL DISCRETION

Discretion in the criminal justice system refers to the capacity of court officials and law enforcement agents to make authoritative decisions in the absence of specified directives and controls. Legal scholar Kenneth Culp Davis emphasized that discretion in the criminal justice system provides prosecutors the freedom to choose what they will rely upon in determining whether government action will be taken against a suspect and how prosecution will proceed if criminal charges are filed.

Associated with discretionary decision-making is uncertainty about what case information, institutional constraints, and external forces influence prosecutors' decisions. Unlike in other Western democratic countries, in the United States, prosecutors at both state and federal levels exercise wide latitude of discretion in deciding to prosecute, the level of criminal charges and number of counts filed, whether criminal charges are later dropped, pretrial detention recommendations, whether a guilty plea offer is accepted, and the terms of guilty plea settlements. In addition, prosecuting attorneys influence sentencing decisions through their discretion to recommend severity of punishment and motions for various departures

from sentencing guidelines. The latter exercise of prosecutorial discretion rewards defendants who provide substantial assistance in arrest and conviction of other criminal defendants and for defendants who cooperate with the prosecutor by pleading soon after criminal charges are filed.

Legal scholars note that prosecutorial discretion is essentially unreviewable except by prosecutors internal to the prosecutor's office. This broad, virtually unfettered scope of prosecutorial discretion in state and federal courts is derived from a series of Supreme Court decisions and federal and state appellate court holdings dating to 1883. As a result of court holdings, a U.S. prosecutor's exercise of discretion is essentially free from judicial review. Thus, U.S. prosecutors occupy a central and powerful position in the criminalization process, from the decision to prosecute through sentencing. This entry presents research on the variables that influence prosecutorial discretion in state and federal courts.

Qualitative Research on Prosecutorial Discretion

In the late 1960s, social scientists began studying the variables influencing prosecutors' exercise of their discretion. Early research used ethnographic studies to describe the dimensions of prosecutorial discretion, especially the decision to file criminal charges. Using interviews with prosecuting attorneys, judges, and law enforcement officials, as well as participant observation of court officials, researchers found that seriousness of the alleged offense and evidentiary strength of the case increased the probability of prosecutors filing criminal charges.

David Neubauer's research revealed the often tense relationship between prosecuting attorneys, who must make charging decisions in light of the probability of conviction, and police, who expect those arrested to be charged. At the center of this tension are different priorities. Rank-and-file police assume that their decision to arrest a suspect is factually accurate, while prosecuting attorneys must attend to determining the likelihood of success at trial, the legal arena where the government's evidence against the defendant is tested against high legal standard of proof beyond a reasonable doubt. Even though the vast majority

of criminal charges are disposed of via a guilty plea, prosecutors use assessments of their chance of winning at trial as the reference for deciding to charge a suspect with a crime. Rank-and-file police expect prosecutors to file charges against all suspects arrested, while prosecutors are concerned with their ability to obtain a conviction. Although the tension between police and prosecutors described by Neubauer applies to the relationship between rank-and-file police and prosecutors, other research points to a different relationship between prosecutors and specialized investigative agents.

Sociologist Boyd Littrell's research observed that prosecutors are dependent on detective bureaus to build a prosecutable case based on evidence that will sustain trial disposition. Central to Littrell's *bureaucratic justice* perspective of criminal prosecution is the combined role that law enforcement detective bureaus and prosecutors play in managing the construction of prosecution and adjudication. He argues that a prosecutor's decision to charge is often surrounded by ambiguity arising from constructing past events. Specialized detective bureaus influence prosecutorial decisions by shaping the type of evidence presented to the prosecutor. Littrell postulated that prosecuting attorneys rely on specialized detective bureaus to manage the inherent uncertainty of reconstructing past events related to the alleged crime.

Early research that used ethnographic and case history methodology to study prosecutorial decision-making provides sound empirical foundations for subsequent research using quantitative methodologies. This early research provided rich descriptions of the scope and operation of prosecutorial discretion. By doing so, qualitative research stimulated quantitative investigation of the net effect of defendant characteristics and case information on prosecutorial discretion.

Quantitative Analyses of Prosecutorial Discretion

Research focusing on prosecutorial discretion shifted from primarily ethnographic methods to advanced statistical analysis in the late 1970s. A substantial number of studies contributed to further understanding of prosecutorial discretion at

both the state and the federal levels of criminal adjudication. This body of research included analysis of prosecutorial discretion to file criminal charges, to *nolle prosequi* (drop charges), to file motions for departures from presumptive and advisory sentencing guidelines, and to impose three-strikes statutes. With enactment of the federal sentencing guidelines in 1987, a substantial body of research focused on the increasing latitude of discretion federal prosecutors' exercise in determining sentencing outcomes by filing motions for substantial assistance departures.

Drawing from the *bounded rationality* theoretical perspective of decision-making in people-processing organizations, sociologist Celesta Albonetti theorized that case information that increases the uncertainty of obtaining a trial conviction would significantly increase the probability of prosecutors filing initial criminal charges and their decision to drop charges after indictment. She argued that type and strength of evidence, the victim–defendant relationship, warrantless arrests, and whether the victim provoked the alleged offense are related to prosecutors' assessment of uncertainty of obtaining a conviction. As such, these variables are hypothesized to affect prosecutors' exercise of charging discretion. Her analysis of assistant U.S. attorneys' decisions to *go forward* with criminal charges in felony cases processed in the District of Columbia during 1974 supported her theory of uncertainty avoidance. Specifically, Albonetti found that the presence of exculpatory evidence and physical evidence exerts significant increases in the probability that criminal charges are filed. Consistent with expectations, the presence of corroborative evidence significantly reduces the probability that an assistant U.S. attorney files charges. Her research reveals that cases with one witness or cases in which the victim is the only witness significantly reduced the probability of prosecution, compared to cases with more than one witness. This finding is consistent with Littrell's assertion that prosecutors' assessment of uncertainty is heightened in cases with only one witness.

Albonetti's study found that case information related to prosecutors' assessments of uncertainty significantly affects their decision to discontinue prosecution. Prosecutors were more likely to file criminal charges in cases involving victims and

defendants who are strangers. In cases involving defendants and victims who are acquaintances or intimates, prosecutors were significantly less likely to file charges, controlling for the type and strength of evidence. Cases involving victim provocation increase uncertainty of obtaining a conviction. As such, prosecutors are significantly less likely to prosecute. Taken together, these findings provide empirical support for the uncertainty avoidance theoretical perspective of prosecutorial exercise of discretion. These findings reveal how prosecutors use their wide discretion to manage uncertainty in deciding to prosecute charges and to drop charges after indictment. Controlling for the aforementioned variables, prosecutors were less likely to file charges against females, compared to males.

Cassia Spohn, Dawn Beichner, and Erika Davis-Frenzel's research on prosecutorial discretion in sexual assault cases in 1997 in Miami, FL, found that prosecutors were more likely to bring charges when the suspect used a weapon, when the victim was injured, and in cases involving acquaintances, relatives, or an intimate partner, compared to strangers. Their multivariate analysis indicated that the victim's and suspect's race and age did not exert significant effects on the prosecutors' decisions to file charges. Spohn, Beichner, and Davis-Frenzel's analysis found no significant effect of physical evidence on prosecutors' decisions to file charges. Also, they found that having a witness to the alleged incident and victim's resistance to the sexual assault did not significantly affect prosecutors' decisions to go forward with criminal charges.

Prosecutorial discretion influences sentence severity through charge reductions and guidelines departures. Lauren O'Neill Shermer and Brian D. Johnson's study of charge reductions in U.S. federal district courts found that federal prosecutors were more likely to reduce felony charges for young White females, young Hispanic females, and older Hispanic females, compared to older White males. Compared to non-U.S. citizens, U.S. citizens were less likely to have charges reduced. The higher the number of filing charges, the defendant's acceptance of responsibility, increases in offense severity, property charges, fraud charges, and the use of a weapon increased significantly the odds of a charge reduction. Noteworthy is their finding that defendant's marital status and

level of educational achievement had no significant effects on the odds of a charge reduction. Defendants charged with an immigration violation had a decrease in the odds of a charge reduction. O'Neill Shermer and Johnson's research further indicates that prosecutors' decisions to reduce charges significantly reduces length of imprisonment, controlling for defendant characteristics, type of offense, defendant's criminal history, and departures from the federal sentencing guidelines presumptive sentence.

Federal prosecutors exert influence over sentencing by charge reductions and by departure motions for defendant's substantial assistance to the government in the prosecution and conviction of other defendants. As noted earlier, federal prosecutors exercise a wide latitude of discretion in deciding to file substance assistance departures. These departures significantly reduce length of imprisonment, controlling for defendant characteristics, legally relevant case information, and process-related variables, such as whether the defendant pleads guilty and accepts responsibility for his or her illegal behavior. Research indicates that federal prosecutors are less likely to file a motion for a substantial assistance departure in cases involving Blacks or Hispanics, compared to Whites. Further research is needed to examine what accounts for this finding.

Political scientist Elsa Chen examined the variables influencing prosecutors' decisions to avoid application of California's "Three Strikes and You're Out" law. California's three-strikes law permits prosecutorial discretion in deciding to apply the law by allowing the prosecutor to dismiss or strike a prior felony conviction that would otherwise trigger application of the mandatory three-strikes sentence. Chen's study of prosecutorial discretion in 56 of the 58 California counties found that prosecutors were less likely to dismiss a prior conviction for African American defendants, compared to White defendants. Consequently, African American defendants experienced greater exposure to three-strikes sentencing. She found that charges for serious or violent offenses significantly increased the odds of applying the three-strikes law. Charges for less serious property and drug possession offenses significantly reduced the chances that prosecutors applied the three-strikes law. Moreover, she found that prosecutors

in more politically conservative counties were more likely to apply the three-strikes law.

Final Thoughts

Research by sociologists, legal scholars, and political scientists reveal the broad scope and wide latitude of prosecutorial discretion in state and federal criminal adjudication. There is virtually no stage of the U.S. criminalization process that is untouched by prosecutorial discretion. The low visibility of prosecutors' decision-making challenges research efforts to empirically examine the effects of defendant characteristics, case information, and political environment on the exercise of prosecutorial discretion. Thus far, qualitative and quantitative research indicates that prosecutors use their discretion to manage uncertainty in obtaining a conviction. Furthermore, research points to mixed finding of the relevance of defendant characteristics on prosecutors' decisions to file charges, to discontinue prosecution after indictment, and to reduce charges.

PROSTITUTION

Prostitution is broadly defined as the performance of sexual acts for financial remuneration. It is estimated that 40–42 million people engage in prostitution worldwide, though exact numbers are difficult to ascertain because prostitution is largely illegal, involves criminal networks, and is associated with human trafficking. Discourse regarding prostitution has predominantly focused on street prostitution, despite it being the least prevalent form of sex work. Other forms include brothel work, escorting, call boy/girl rolls, massage parlor workers, and gender performers. This does not include managers and pimps (indirect participants in the sex industry) nor customers who pay for sexual services. Although primarily focused on the academic discourse regarding prostitution, this entry also discusses risk factors, differences among the various types of prostitution, and future research directions.

Discourse

Prostitution is situated within a moral, sociopolitical milieu, which affects the legal standpoint of, and interpersonal relationships between, sex workers, law enforcement, and the public. Public opinion of prostitution sits within a broader discourse of gender norms, sexuality, power dynamics, finances, and *acceptable* sexual behavior. Evolutionary research has shown that this discourse is affected by the value placed on female virginity, which may result from paternity uncertainty. This has resulted in a historical stigmatization of female sexuality and continued stigmatization of sex work. There is also a view that women should not want sex or money unless motivated by nurturing

intentions. This may explain why prostitution, involving both, is viewed negatively by the public, irrespective of the laws of the region, particularly when it is *indiscreet*, as in street prostitution. It may also explain why research often discusses sex work as devaluing women by selling something integral to the self, despite the same language not being used for other work.

Like other gender-sensitive areas (e.g., domestic abuse), research on this subject has been dominated by feminist arguments, focusing on patriarchal ideals, conceptualizing prostitution as framed within this unequal gender dynamic, whereby women are dominated, victimized, and controlled by men. Radical feminist arguments regarding prostitution have been criticized because they are not evidence based and are often inconsistent with research. They tend to focus on, and possibly exaggerate the occurrence of, human sex trafficking and other negative aspects of sex work. This may explain why street work receives greater attention, as exploitation and risk are highest in this group.

Researchers often recruit former sex workers who consider themselves victims to conduct interviews on their behalf, which can result in leading questions. This practice can encourage bias and fails to take into account multiple types of prostitution, including male, homosexual, or transgender sex workers. Problems within feminist-based explanations of prostitution are evident when, for example, male prostitution is explained using a standardized framework, claiming that male prostitutes exploit usually very wealthy, older female clients. That is not to say exploitation does not occur, only that research should be evidence based, and theories of prostitution must be inclusive of all types of sex work and sex workers. In order to understand the interpersonal dynamics of prostitution, neglected groups need to be included, as do managers and customers.

Beyond *women as sellers; men as buyers*, definitions of prostitution are comparatively limited. This is reflected in a limited body of research on male prostitution, which has historically (before 2005) received considerably less attention. Male sex work and sexual exchange (i.e., providing sex for resources, such as food or drugs) include sexual escorting practices as well as *gay-for-pay* prostitution or pornographic acting. Prostitution spans

a range of sexualities and encompasses sexual fluidity, yet these have seldom been studied. Transgendered prostitution, for example, has received very little empirical attention, although some studies have emerged since around 2014. This has partly been blamed on the widespread criminalization of prostitution, tacitly promoting heteronormality through even greater fear of reprisal and suppression, driving LGBTQ (Lesbian, Gay, Bisexual, Transgender, Transsexual, Queer) prostitution further underground.

It has been argued, including by gender performers, that sex work is almost exclusively seen as taking place within heteronormative economic relationships. This includes a stereotypical power dynamic whereby men possess control. However, it has also been argued that prostitution flips this dynamic because male sexual desire is used to gain money, which is a form of power within capitalist cultures. Gender performers actively reject these gender norms and try to move beyond them in their acts. Sex as a commodity is still present in their performances and is a large part of public dialogue regarding sex work. However, gender performers use props and swap out gender assignment to show bidirectional and multiform sexual and sociosexual power. Future research is needed to explore public discourse in this area because it is integral to the context and impact of sex work.

Risk Factors

While radical feminism sees sex work as part of the patriarchal exploitation of women, the public largely views sex workers as criminals, which impacts the political and legal landscape within which prostitution takes place. It exacerbates the known risk of egregiously violent robbery, assault, rape, and murder. There is also a comorbidity of substance and alcohol abuse, criminal activity, poverty, homelessness, and sexually transmitted infections, particularly among young female street workers and transgender sex workers. Moreover, the decision to engage in prostitution typically involves less freedom for street workers and a greater risk of force or fraud.

One of the reasons that street prostitution has heightened risk is the locales and circumstances in which it takes place. For example, downtown Vancouver's East Side has a high incidence of

prostitution and the lowest average income in Canada as well as one of the highest rates of hepatitis and HIV infection in the Western world. Street workers also engage in riskier behaviors: frequenting high-crime areas alone, working at night, and getting into cars with strangers. Street and transgender workers, particularly those with prework vulnerabilities such as dependence issues, are known to engage in riskier behaviors and accept lower remuneration. Moreover, public advocacy that shuts down brothels or causes the police to drive prostitutes out of residential areas prompts dispersal into ghettoized areas of cities where poverty, homelessness, addiction, and mental illness are highest.

Risk is particularly dependent on the type of sex work and sex worker, with an ascending level of risk from massage escorts, massage parlor workers, brothel workers, and street workers. In part, this is because protective factors are present for indoor sex workers, such as panic buttons and surveillance equipment in Nevada's legal brothels. The type of sex work performed is related to access to protection, freedom to refuse clients or engage in certain sexual practices, and dependence on third parties. Male prostitutes are generally at lower risk of assault, harassment, and arrest and experience greater mobility across the different types of sex work, than female, homosexual, and transgender workers. Risk is also dependent on race, age, appearance, and income, with the most vulnerable group being transgender workers.

Tensions between sex workers, police, and the public are seen by some as justification for aggression against prostitutes. This relationship is supported by increasing public advocacy against prostitution being followed by increased violence and homicide rates. It has also been argued that police are less diligent in their investigations, applying less crime linkage, when the victim is a prostitute. The example of the epidemic of Aboriginal sex workers that went missing in the 1990s in Vancouver has been cited as evidence, as have the very low rates of prosecution and conviction in cases involving sex workers. The risk of arrest also results in underreporting of crimes by sex workers. There is some evidence that having a pimp can be beneficial in protecting against these risk factors because pimps often

enforce no-drug policies and promote safety behaviors, such as working in pairs. However, reports from prostitutes also suggest that pimps victimize workers and do not increase feelings of overall safety.

Risk factors have led feminist advocacy groups to campaign for prostitution's decriminalization. There are already some countries and regions where prostitution is legal. For example, it is legal in the Netherlands; some forms are decriminalized in some Australian states; Nevada, in the United States, has legal brothels; and some European countries have decriminalized third-party involvement in prostitution. Some studies have found lower rates of prostitution where it is illegal, but this relationship is not causal, is not strong, if present, and is affected by the purpose of the research, with most studies focusing on harm reduction or those who want to get out of prostitution. Moreover, gaining access to populations is difficult where prostitution is illegal, which may result in underestimates in those regions, hampering efforts to ascertain the effect of decriminalization.

Furthermore, there is mixed evidence that decriminalization results in decreased risk factors. Some studies suggest safety is improved, particularly where decriminalization moves prostitution off the streets; however, this is dependent on the type of prostitution and licensing policies involved. For example, where legalization is heavily regulated via licensing brothels, as in Victoria, Australia, street prostitution may increase, due to licensing being dependent on no drug use and no previous arrest policies, which may hamper safety, driving the most vulnerable sex workers onto the street. This is also seen by the public as condoning prostitution. There is also evidence that legalization improves working conditions and worker benefits for sex workers. However, decriminalization does not necessarily decrease crime or sex work arrests, with the number of street arrests remaining consistent in areas where licensed brothels have been introduced (e.g., Victoria and Queensland, Australia). The effect of decriminalization seems largely dependent on the preexisting relationship between the police and sex workers. Research also needs to look at customers, who outnumber prostitutes, and their varied motivations and experiences.

Individual Differences

As noted, the way contemporary prostitution is conceptualized can be limited. Sex work for money and sexual exchange are not wholly distinct. One example, related to the rise of the Internet, is webcam modeling, or *camming*. Camming, which attracts models from across the world, may be sexual or nonsexual, but the most successful cam artists typically fall into the former category. Camming of this nature typically involves individual women or men performing sexual acts, often chosen by their remotely based audience. Performers can receive money from viewers; often, they are gifted indulgent material goods, selected from a wish list they have curated. Sometimes, these gifts are sexually themed (e.g., sex toys, underwear); frequently they are not (e.g., games consoles). Sexual camming of this kind is thus used by some models as a proxy that negates complex legal issues surrounding the transactional provision of sexual acts in many territories. Big monetary donors to top cam models (who can receive US\$75,000–US\$100,000 per month) may *win* the right to an in-person *date*, for example. Notably, these will often take place in specific territories where prostitution is legal (e.g., Nevada). Moreover, models may provide online encouragement, support, and advice for one another, which is criminalized in some formal sex work.

Camming illustrates that contemporary prostitution is more than just selling sex for money: The express nature of sexual exchange may vary from sex work but shows how the two may interrelate and overlap and shows the need for a revised definition of *prostitution*. Within traditional sex work, the behaviors undertaken vary greatly, with call girls often offering *the girlfriend experience*. These different activities affect the impact that sex work has on the workers' physical and mental well-being. Prostitution is not a universally gendered, exploitative construct detached from consent. In particular, with more individuals actively choosing to engage in sex work or sexual exchange of some kind, the variations in predictive factors that account for their choices are increasingly relevant. Advances in the study of personality have provided some clarity in this respect.

Research on three subclinical personality traits—narcissism, Machiavellianism, and psychopathy—collectively known as the *Dark Triad* may be vital

in understanding prostitution. These traits are related, but distinct, and predict unique and overlapping outcomes. Narcissism is related to materialism as well as a wish to be seen as sexually desirable. Machiavellianism predicts behavioral flexibility: a drive to act in ways perceived as most beneficial to oneself. Psychopathy predicts impulsive, sensation-seeking behaviors (including criminality) and an emotionally detached, cold approach to life and interpersonal relationships. Psychopathy has also been related to substance use, which motivates and facilitates some individuals taking up prostitution. All three predict an unrestricted sociosexuality, relating to a willingness to engage in frequent and various short-term mating scenarios (e.g., booty call, friends with benefits relationships) in women and men. In sum, they account for a wide range of variance in the factors that have been found to predict sex work and sexual exchange.

Future Research Directions

There are both broader and deeper issues that surround prostitution and intersect with its widespread criminalization. There is a need to move beyond a one-size-fits-all theory of prostitution and to look at the motivations, behaviors, and interpersonal interactions of customers, managers, police, public, researchers, and all different types of sex workers. There is also a need to look more broadly at the impact of prostitution, including the effect that sex work has on the families and children of those involved. A growing body of work that adopts a postfeminist, pansexual, and evolutionary personality-informed approach seems to be emerging, however, expanding the understanding of prostitution in multiple important directions.

PROTECTIVE FACTORS, DEFINITION OF

Protective or strength factors represent conditions that reduce the likelihood an individual will engage in antisocial behaviors. On the contrary, criminogenic risk factors represent characteristics of an individual or his or her circumstances that increase the likelihood of engaging in criminal or other antisocial activities. A history of conduct disorder, school failure, substance abuse, and negative peer associations are examples of risk factors.

Some debate exists regarding the appropriate way to conceptualize protective factors. In some cases, protective factors are represented in terms of the absence of a risk factor. For example, substance abuse is treated as a risk factor, whereas the absence of abuse is treated as a protective factor. In other cases, protective factors are viewed as independent of risk factors but are seen as operating to moderate or ameliorate the risk. For

example, a positive relationship between parent and youth accompanied by positive parenting may serve as a buffer against exposure to negative or antisocial peers. Similarly, a job skill and positive attitude toward work may serve as a buffer against influence from a criminogenic neighborhood. The treatment of protective factors as mediators of risk factors is the usual practice in the literature. However, some controversy also exists regarding the way in which risk and protective factors interact to affect behavior.

The identification of protective factors is important from a number of perspectives. First, to the extent that these factors play a role in determining the likelihood of engaging in antisocial activities, combining them with identified risk factors can improve the accuracy of predictions. Second, the identification of protective factors can play an important role in case planning and management. The Risk-Need-Responsivity model asserts that effective interventions are based on assessments of risks (factors placing the individual at risk of criminal activity), needs (risk factors that can be changed to reduce risk), and responsivity factors (factors not directly related to the criminal activity but that are relevant to case planning). Strength or protective factors are included in the latter category. This means that effective programs are strength based; that is, they incorporate positive features that an individual brings to the situation. Finally, identification of positive features of an individual or his or her situation is important when a psychologist is establishing a relationship with a client. A purely negative approach in dealing with individuals is rarely effective.

While considerable research has been conducted on risk factors, less attention has been paid to the identification of protective factors. However, operational definitions are represented in several instruments specifically designed for assessing protective factors (e.g., Structured Assessment of Protective Factors for Violence Risk) and broad-based risk-need instruments that include indices of strength (e.g., Level of Service/Case Management Inventory; Youth Level of Service/Case Management Inventory 2.0). Broad categories of protective factors in these instruments include features of the individual’s environment (e.g., family supports, positive peer associations, educational and mental health resources) and

characteristics or traits of the individual (e.g., emotional maturity, interest in hobby or sports, prosocial attitudes and values). It is important to recognize that protective factors relevant to a particular case will depend on a number of factors, including age or developmental level. Positive parenting and a good relationship between parent and youth may be important protective factors for an adolescent but may not be relevant to an adult.

Two broad constructs are relevant to protective processes: resilience and social capital. Resilience is treated as a characteristic or trait of the individual reflecting a capacity to cope effectively with conditions of stress or adversity. The second construct, social capital, refers to a constellation of personal characteristics reflecting high levels of coping skills, maturity, and prosocial attitudes. Both constructs, resilience and social capital, are important in helping psychologists understand why some individuals are better at coping with risk factors than others.

Much research and clinical attention has focused narrowly on the analysis of risk factors. However, increasing attention is being paid to the strengths a client brings to the situation. While there remain theoretical issues yet to be resolved, it is generally recognized that the prediction of criminal activity and interventions to address criminogenic needs can be improved by acknowledging the importance of these positive factors.

PROTECTIVE FACTORS AND RELATIONSHIP TO RISK

Identifying and treating the problems or factors related to criminal and violent behavior are important for both prevention and intervention. Likewise, identifying and increasing protective factors—those factors that make it less likely that an individual will engage in criminal or violent behaviors—are developing strengths in significance. This entry reviews the rationale for considering protective factors in risk assessments and then discusses the conceptualization of protective factors and the application of protective factors in risk assessments.

Protective Factors and Risk Assessment

Historically, forensic and correctional psychologists have attempted to reduce recidivism by utilizing a deficit-based model that prioritizes the identification of risk factors. Risk factors have been defined as factors that provide information about who is likely to engage in criminal and violent behaviors. There have been numerous prospective longitudinal studies aimed at identifying risk factors associated with violence. Risk assessment researchers have demonstrated that the cause and continuation of violence are determined by a combination or interaction of individual, historical, and environmental factors. Certain personality factors (e.g., risk-taking, low self-control), historical factors (e.g., family of origin violence, age at first offense), and environmental factors (e.g., antisocial peers) increase the likelihood of violence. The higher the level of risk factor (e.g., high levels of hostility), or the greater number of risk factors one exhibits (e.g., high levels of hostility, young, and antisocial peers), the greater the likelihood that the individual will engage in criminal or violent behavior.

Since the 1980s, research has focused on risk variables, allowing for the development of several

risk assessment instruments, as well as target areas for offender treatment and management. Risk prediction has been helpful, allowing forensic examiners to assign risk levels to violent and sexual offenders and providing experts with key testimony artifacts for court proceedings. However, the success has been moderate. Although the *best* risk assessment instruments account for significant prediction (better than chance) for criminal and violent behavior, there remains a significant portion of explanation left to understand and increase the accuracy in predicting who will exhibit violent behavior. For example, if risk variables account for approximately 70% of the *pie* of prediction, 30% remains unexplained. If one applies this deficit-only model to finances, focusing only on debt would provide a bleak and hopeless economic future. Similarly, in understanding an individual's likelihood to engage in violent behavior, examining only their deficits eliminates important information from the equation.

Hence, researchers have developed a greater understanding of the importance of protective factors or strengths that may either serve to prevent an individual from engaging in criminal or violent behavior initially or serve to reduce the likelihood of an offender continuing to commit criminal or violent offenses. Protective factors are environmental and individual factors that *protect* people from committing criminal and violent behaviors. Positive social influence represents one of these factors. Researchers have consistently found that having friends and family who are a prosocial, supportive influence serves to prevent criminal behavior as well as buffer high-risk offenders against reoffending.

There are several important reasons as to why it is essential to consider protective strengths in the assessment process. First, as stated earlier, including strengths serves to increase prediction accuracy. Researchers report that utilizing the combination of risk and strengths together is a better predictor than risk, or deficits, alone.

Second, examining only an individual's deficits (risk factors) will most likely lead to overprediction of risk. Without examining strengths, the deficit model will predict higher levels of criminal or violent behavior compared to when strengths are similarly accounted for. Researchers have demonstrated that there is such a thing as too much

treatment. Some individuals may actually be worse off if mandated to engage in a treatment *dose* that is above what is actually needed. This overprediction is costly for both the offender and the society.

Third, overprediction of risk may be stigmatizing for individuals in the criminal justice system; clients have reported that the constant focus on their deficits increases negative self-evaluation. In addition, if risk levels are inaccurately overpredicting, offenders labeled as high-risk level may be required to engage in further stigmatizing actions that can diminish their chances of success in the community. For example, sexual offenders who are deemed high risk on the public registry may be required to send a postcard to all of their neighbors informing them that they are sexual offenders. While this may be helpful in reducing recidivism for truly high-risk sexual offenders, it may be harmful to the success for the sexual offender who is not actually high risk.

Finally, the identification and assessment of protective strengths afford treatment providers and offender managers (e.g., parole and probation officers) with important areas to address in efforts to reduce future criminal and violent behavior. This allows for an increased number of areas to *treat* or build in order to decrease the likelihood of further criminal and violent behaviors as well as providing offenders positive areas of focus rather than solely on negative or deficit issues. This is consistent with several newer offender treatment approaches focusing on the enhancement of well-being and aimed at building motivation and rapport.

Conceptualizing Protective Strengths

If protective strength factors are defined similarly to risk factors, protective strengths are individual, historical, and environmental factors that decrease the likelihood of a person engaging, or continuing to engage, in criminal or violent behavior. Researchers have proposed that there may be protective factors that are static and dynamic, similar to risk factors. For example, the development of secure attachment style in childhood and having prosocial parents are protective strengths that remain constant, whereas current peers and levels of self-control are dynamic. Criminologists would contend that external or environmental factors are

more important than internal or individual factors, and forensic psychologists would argue that internal factors, such as personality factors, are more predictive. Historically, criminologists have examined variables as they relate to crime desistance, and forensic psychologists have focused on factors that serve to protect an individual from recidivism. Although termed differently, these protective variables identified in the two fields are similar, if not identical.

Research in both criminology and forensic psychology has suggested that protective strength factors may act in a few different ways. First, protective factors may simply be opposite of risk factors, variables on the same continuum or scale. An example would be peer influence, where one end is antisocial influence and the other end is prosocial influence. Second, a protective factor may reduce risk but not be related to specific risk factors. For example, religiosity is a protective strength for some people but being nonreligious is not a risk factor. Third, risk factors may only serve to protect from further criminal and violent behavior if the individual is at high risk, having little influence for lower risk individuals. Researchers have also distinguished differences by name, terming helpful factors *promotive* if they are related to reducing reoffending irrespective of risk level and *protective* if they reduce reoffending in more high-risk offenders versus lower risk offenders. Research has not been able to effectively assess whether these are true distinctions in how protective factors may vary in effect. Thus, factors that reduce the likelihood of engaging in criminal and violent behavior, regardless of risk and past convictions, are termed *protective factors*.

There is agreement in the field that protective factors are definable factors, propensities, or manifestations thereof in their own right, not just an absence of risk factors. In addition, protective factors that are related to a specific risk factor may coexist, not exclusively exist on one side of a continuum or the other. For example, an individual could have negative or antisocial influencing peers *and* prosocial peers at the same time.

Protective Strengths in Juveniles

The relationship between protective factors and desistance from crime and violence in juvenile

populations has been documented long before assessment of these factors in adults. Hence, the literature for protective factors of juvenile offenders is superiorly developed and has served to inform research with adults. This advancement stands true for adolescent risk assessment as well. As adult assessment instruments have recently begun to include protective strength assessment, juvenile assessment measures have included protective factors for some time. Protective strengths in juvenile assessments include variables that have demonstrated some significant relationship with criminal, violent, and/or sexual offending desistance of adolescent offenders. These factors include prosocial involvement (e.g., team sports, organization membership), social support (i.e., people who the adolescent may turn to when in distress or crisis), attachment to prosocial adults, motivation for treatment or change, strong commitment to learning or school, and the traits of resilience and capacity for emotional intimacy. Having a resilient personality seems to be one of the most important factors in crime and violence desistance in juveniles.

Research conducted during the 21st century suggests that certain protective strengths found in juvenile populations may be related differentially to outcome. For example, the ability to attach to others, express feelings, show concern for others, and understand feelings may be more related to desistance in sexual offending compared to other protective factors. In addition, school involvement may have a greater relation to the desistance of general and violent offending behavior.

Protective Strengths in Adults

Similar to research on adolescent offenders, similar categories of protective strengths seem to be related to criminal and violence desistance in adults. For example, attachment and commitment to prosocial people (e.g., peers, spouse) have been related to reductions in recidivism for all violent offender types. Another similar protective concept is employment (instead of school commitment). Offenders who are committed to their job and are successful at obtaining consistent employment are significantly less likely to reoffend. Researchers on adult desistance from crime and violence have reported that aging, marriage or

long-term committed relationships, stable environment, stress-coping skills, sobriety, and good mental health have been associated with the reduction in recidivism. Similar to the construct of resilience in juvenile samples, adult offenders who keep a positive attitude and feel like they have control over their own futures fare better once released from prison.

Of the few measures that include protective factors for adult risk assessment, there are consistent protective factors related to criminal and violence desistance. These include the ability to regulate thoughts, emotions, and behaviors (self-control); prosocial support and attachment; education or training for employment; and stress coping. All of these variables are related to forms of criminal, violent, and sexual offending desistance. Similar to the juvenile literature, research examining protective strengths in adult offenders indicates the potential of protective strengths related to differential outcomes. For example, research has indicated that prosocial attachment, understanding of personal responsibility for behavior, treatment attachment, and a feeling of belonging to a support group were all related to the desistance of sexual offending.

Applying the Protective Strength Approach

Research on protective factors has demonstrated the importance of the inclusion of strengths in risk assessment. Including protective strengths adds incremental validity to the prediction of offending behavior, recidivism, and the desistance of criminal and violent offending with individuals who have previously committed these behaviors. Moreover, the focus and building of protective strengths in treatment opposed to solely focusing on reducing risk factors benefits treatment outcome and allows for increased positive focus in therapy. This in turn benefits therapeutic alliance, which has consistent support in improving outcomes for all clients. The inclusion of protective strengths in risk assessment not only increases predictive accuracy but also serves to inform treatment and management of offenders, increasing effectiveness and desistance.

PROTECTIVE FACTORS ASSESSMENT

Risk management in forensic and correctional populations has traditionally focused on decreasing risk factors for antisocial and aggressive behavior, without paying much attention to increasing protective, strength-based factors. A protective factor is any characteristic of an individual, his or her environment, or situation that reduces the risk of future adverse outcomes. In forensic work, the adverse outcome of interest is

often reoffending. Protective factors moderate or buffer the impact of exposure to risk factors, leading to a lower reoffending risk. This entry reviews the relevance of protective factors for risk assessment in correctional and forensic psychiatric populations, including juvenile offenders and sexual offenders. In a case example, the utility of protective factors assessment for building a positive risk management plan is illustrated.

Risk Assessment and Management

A comprehensive and widely used risk assessment and management model based on theoretical principles is the Risk-Need-Responsivity (RNR) model. In the RNR model, the risk principle asserts that criminal behavior can be accurately predicted and that risk management interventions should focus on the higher risk offenders. According to the risk principle, societal resources should be directed to those offenders at moderate to high risk of reoffending, not to the low-risk cases. The need principle highlights the importance of criminogenic needs, also termed *dynamic risk factors*, because these are the risk factors amenable to change by intervention and risk management strategies. An example of a criminogenic need is substance abuse, and appropriate risk management strategies could be substance use treatment and random urine checks, for example. The responsivity principle describes how treatment should be tailored to the individual offender. Thus, an offender who is intellectually disabled would need a less verbal and more practical approach to effectively change risk factors, compared to an offender of average intelligence. Research has shown that offender rehabilitation programs that adhere to RNR principles are more effective in reducing offender recidivism than those that are not based on RNR.

The RNR model of offender rehabilitation has been complemented by the Good Lives Model (GLM), which is a strength-based approach. It offers guidance to target human goods (i.e., valued aspects of human functioning and living) in offender treatment. According to the GLM, experiences and activities that are likely to result in enhanced levels of well-being should be included when formulating plans for treatment and risk management.

The evidence base for the effectiveness of treatment programs designed according to the GLM is growing. Preliminary beneficial effects of treatments based on GLM principles are higher treatment motivation and engagement among offenders. More generally, higher subjectively experienced quality of life is associated with lower recidivism rates in male forensic outpatients. This implies that improving protective factors that inspire a good life and enhance quality of life leads to reductions in adverse outcomes.

Risk Versus Protection

Structured risk assessment tools have been developed to aid forensic and correctional staff in their day-to-day practice. Since the mid-1980s, the sheer number of forensic risk assessment instruments has increased substantially. There are now literally hundreds of risk assessment instruments for different outcomes including violent outcomes such as general violent offending, sexual offending, spousal assault, stalking, and workplace violence. These instruments have led to an increase in the level of transparency regarding proposed interventions and decision-making, compared to former unstructured clinical risk judgment approaches. However, this so-called culture of risk in forensic psychology and psychiatry has also met with criticism. An extreme focus on risk factors could contribute to professional nihilism and result in offender stigmatization. This has stimulated the development of structured tools for the assessment of protective factors for violence risk, such as the Structured Assessment of Protective Factors for violence risk (SAPROF) and the Short-Term Assessment of Risk and Treatability (START), which in turn has facilitated research on protective factors for reoffending, including violent reoffending, since 2005.

Several studies have found that protective factors indeed provide a buffering effect: Individuals with moderate-to-high risk levels, who also possess high levels of protective factors, show significantly lower recidivism rates than high and moderate risk cases without protective factors. Examples of such buffering protective factors are commitment to structured leisure activities and commitment to school or work. Although research on protective factors in forensic mental health is

still in its infancy, it should alert forensic mental health professionals to the importance of taking protective factors into consideration when performing risk assessments and when implementing risk management and rehabilitation interventions. In addition, a stronger focus on protective factors inspires treatment motivation and alliance for both the professional and the offender/patient.

Protective Factors in Adolescent Offenders

Adolescence is a formative developmental period that provides both obstacles and opportunities for psychological growth. The age range from 12 to 24 is the period when antisocial and criminal behavior peaks. Similar to adults, adolescents possess not only risk factors or vulnerabilities but also remarkable strengths. This was acknowledged in one of the earliest risk assessment tools for adolescents, first published in 2002: the Structured Assessment of Violence Risk in Youth. It includes 6 protective factors and 24 risk factors. The START: Adolescent Version is an adaptation from the START, using a developmentally informed approach. The START and START: Adolescent Version pose risks and strengths as opposing ends of a risk domain. These tools not only focus on risk of violence to others but also take into account other adverse outcomes, such as victimization and risk of suicide.

Contrary to common media images, adolescents who engage in violence are often quite vulnerable and are at high risk of self-injury and victimization. The SAPROF-Youth Version was published in 2014 and is intended to offer a positive addition to violence risk assessment with risk-focused tools in young offenders. It contains 16 dynamic protective factors for juvenile violence risk, such as self-control, school/work, and social support or professional care. The SAPROF-Youth Version and its adult predecessor, the SAPROF, focus entirely on protective factors that have been found to be linked to desistance from offending.

Sexual Offenders

Most life domains that are the focus in protective factors assessment are also valuable for the rehabilitation of people who have sexually offended. Indeed, the SAPROF factors have been shown to be equally predictive of desistance from sexually violent recidivism as well as violent recidivism. On

the other hand, additional sexual offending-specific protective factors may also be important. The protective factors assessment tool for juvenile sexual offenders, the Desistance for Adolescents Who Sexually Harm-13, consists of both general protective factors and factors that promote healthy sexual interests, such as prosocial sexual attitudes. For adult sexual offenders, an additional manual to the SAPROF is also being developed and aims to assess specific protective factors that enhance desistance from further sexual offending.

Case Example

John was a quiet boy who did well in elementary school. His father regularly used drugs and alcohol, which led to conflicts between his parents and ultimately to a divorce when he was around 15 years old. At age 12, John began to exhibit behavioral problems, showing oppositional behavior in school, using soft drugs, and hanging out with deviant peers. At the age of 16, he ended up in prison for the first time for theft. When he got out of prison at age 17, he went straight on to dealing drugs, which culminated in shipping drugs from a Caribbean island to Europe. At 24, he was arrested again, this time for extortion, robbery, and multiple other offenses. During his detention for the latter crimes, John was allowed to go on a leave, an occasion he seized to take a drug shipment to Germany. During this drug shipment, he committed his index offense: attempted manslaughter of a policeman. He was sentenced to 8-year imprisonment and mandatory inpatient treatment. During his treatment, he made a serious attempt to change his life in order to have a prosocial future. Several months ago, he was released on probation. The probation service commissioned a forensic psychologist to design a risk management plan to facilitate a safe return to society. Before developing the risk management plan, the psychologist performed a risk assessment, which included a focus on both risk factors (coded with the Historical-Clinical-Risk Management-20 Version 3) and protective factors (coded with the SAPROF).

Historical-Clinical-Risk Management-20 Version 3

The most salient historical risk factors that emerged from the Historical-Clinical-Risk Management-20 Version 3, risk-focused assessment,

were past violence, past antisocial behavior, relationship problems, personality disorder, problems with substance use, employment problems, traumatic experiences, and prior supervision failure. The dynamic risk factors that still play an important role for John are lack of personal support (his current girlfriend has major mental health problems and he has no real friends) and lack of insight regarding the risk of substance use.

SAPROF

The most important protective factors that show from John's SAPROF assessment are as follows:

- *Secure attachment in childhood:* John had a good relationship with his mother and his grandmother during childhood.
- *Empathy:* John shows sincere remorse for his actions and seems to realize that he hurt many known and unknown people.
- *Self-control:* He is effectively working to change his behavior; he has successfully participated in aggression management training and manages to remain calm when provoked or agitated.
- *Motivation for treatment:* John is highly motivated for ongoing voluntary outpatient treatment; he is actively looking for an outpatient therapist.
- *Attitudes toward authority:* John deals well with authority; he accepts guidance, shows initiative, and keeps agreements and promises.
- *Life goals:* He has a positive life goal to devote more time to his role as a father. He wants to be there for his children and provide a good example for them. John indicates he has a Christian faith, and he has received support from his conversations with the priest.
- *Professional care, living circumstances, and external control:* John is currently living in an open rehabilitation home, with continuous monitoring, assistance, and guidance.

Risk Management Plan

To reduce John's recidivism risk as much as possible and to strengthen the protective factors, the following plan was designed:

John currently has no stable employment and does not take part in structured social leisure activities, while these are important protective factors. Furthermore, his social support network is very limited. Although he is supported by his family members, most of them live far away. It would be valuable for him to build a local network of prosocial contacts who can support him in attaining his positive life goals. Participation in work or leisure activities could provide an opportunity to meet new people. His probation officer assists John in finding a suitable job. In addition, he is stimulated to join a football or baseball association, two sports that interest him. Perhaps John could acquire prosocial contacts via the church as well, for example, by participating in discussion groups. John wants to follow vocational training to become a plasterer. This goal seems realistic in relation to his skills and healthy work ethic. However, he has never worked in any steady, long-term employment, so finding a suitable position which is not overly demanding seems of vital importance. His probation officer will assist John in seeking an outpatient therapist and providing a gradual transfer of care.

The results from the risk and protective factor assessment were written up in a report, which were then discussed with John and shared with his new therapist, in order to ensure transparency and continuation of his positive development.

PSYCHOANALYTIC THEORY OF CRIME

Psychoanalysis, developed by Sigmund Freud in the late 19th and early 20th centuries, is the original model of clinical psychotherapy. Since Freud's time, numerous thinkers have contributed to the theory and numerous schools exist under the psychoanalytic umbrella. Although there are significant differences between psychoanalytic theories, they have a number of tenets in common, specifically:

1. An assumption that a significant amount of mental processing occurs outside of awareness. The mental space in which this processing occurs is called the *unconscious*.
2. The assumption that numerous mental processes occur simultaneously and some conflict with each other; the mind makes compromises between them.
3. Childhood plays a significant role in the development of adult personality.
4. Mental representations of self, others, and relationships guide interactions with others and influence psychological symptoms in psychopathology.
5. Psychological development follows a trajectory.

Another commonality among psychoanalytic theories is that they tend to accept Freud's structural theory of the mind, which consists of the id, the ego, and the superego. The *id* is the pleasure principle, or irrational emotional impulse, originating in the unconscious. The *ego* is the reality principle, which organizes the experience of reality and exists in the preconscious and conscious. The *superego* is the internalized rules and norms of one's family and culture, existing at all levels of consciousness. Conflicts occur between the id and the superego and are mediated by the ego. When the ego has difficulty resolving conflicts, symptoms, including criminal behavior, may develop.

Psychoanalytic theory informs criminal psychology because it provides a framework for understanding the conscious and unconscious aspects of the mind of criminals. It should be noted that psychoanalytic theorists tended not to do empirical research as much as theorists from other psychological, sociological, or criminological disciplines in the 20th century and that the theory is largely individual-specific and supported by case studies. That is, it is a psychological theory more than a social psychological, sociological, or criminological theory. This entry provides an overview of the psychoanalytic tenets mentioned earlier and how they relate to criminal psychology and criminal behavior.

Psychoanalytic Tenets and Criminality

The Unconscious

In psychoanalytic theory, awareness exists on a continuum from the conscious (normal awareness), the preconscious (awareness with some prompting), and the unconscious (awareness of only some aspects through psychoanalysis). Information (e.g., thoughts, emotions, sensations, urges,

or externally generated events) considered too painful or threatening to be in conscious awareness is repressed into the unconscious. The original goal of psychoanalytic therapy was to make the unconscious conscious in a way that the individual could tolerate and provide more effective compromises between intrapsychic conflicts.

Criminal behavior, like other behavior, has both conscious and unconscious motivations. That is, criminals may be unaware of their motivations for committing crimes. When interviewed, criminals often have difficulty explaining why they committed crimes in their particular ways. Understanding a criminal's developmental history, relationship patterns, self-concept, perception of others, and current situation can help shed light on potential unconscious motivations for their crimes.

Compromise Formations

One function of the ego is to find a way to make the expression of unconscious urges, wishes, and emotions acceptable. Compromise formations are the way in which these unconscious elements are expressed. The adaptiveness of compromises depends on the capacity of the ego; less ego capacity means less adaptive compromises. Less adaptive compromises generally include more direct expression of unconscious emotions or urges (id impulses). The ego allows expression of unconscious id impulses through dreams, *Freudian slips* (accidentally saying or doing something related to one's psychological conflicts rather than the issue at hand), or, more commonly in criminals, in criminal behavior or psychological symptoms.

Freud did not devote much writing to criminal psychology, although he wrote that criminals suffer from an excess of unconscious guilt and commit crimes in order to be punished for them. This hypothesis has not been supported by research and is not a belief held by most psychoanalytic or psychodynamic forensic psychologists. However, crime can be a compromise formation, if the criminal behavior is an attempt to reduce intrapsychic conflict.

Compromise Formations and Crime

When criminal behavior is committed as a compromise formation, the compromise is usually less adaptive, meaning the unconscious urge is

expressed relatively directly and/or immediately. A noncriminal example of a conflict and its compromise could be a man who is highly conflicted about his homosexual urges (e.g., the unconscious urges include sexual desire, guilt, and hate). He marries a woman, attends a socially conservative church, and financially supports political parties with homonegative policies in an unconscious effort to convince himself that he is not homosexual. A criminal example of compromise for this same conflict could involve the individual engaging in risky one-night stand heterosexual encounters and also sexually assaulting homosexuals to convince himself that he is heterosexual and that, rather than being sexually aroused by homosexuals, he hates them.

Individuals who engage in frequent criminal behavior tend to be impulsive. Their compromise formations likely focus on satisfying immediate urges rather than long-term goals. Resolving conflicts in favor of immediate emotional urges or in ways that express the unconscious urge or feeling more directly can result in dysfunctional relationship patterns as well as limited education and occupational instability, all of which are predictive of criminal behavior. Substance use can also be a compromise that offers a reliable escape from psychological difficulty and also predicts criminal behavior.

Defense Mechanisms

Defense mechanisms are a form of compromise formation. They are relatively unconscious psychological reflexes that distort the experience of internal or external reality to reduce conflict or negative affect. Other theories of criminal thinking patterns use different language (e.g., cognitive distortions, thinking errors), but the concepts largely mirror psychological defense mechanisms without the assumption of an unconscious. Defense mechanisms that have been found to be characteristic among criminals include

- *acting out*, in which the unconscious urge is expressed directly without regard for consequences;
- *passive aggression*, in which aggressive impulses are expressed indirectly;
- *projection*, in which the individual's attributes are projected onto another or others;

- *denial*, in which an aspect of reality is denied;
- *splitting*, in which the self or other is alternately experienced as all good or all bad;
- *grandiosity*, in which one's self-perception is distorted to minimize flaws and inflate strengths;
- *devaluation*, in which positive aspects of another or others are ignored and negative aspects amplified or invented;
- *idealization*, in which negative aspects of another or others are ignored and positive aspects amplified or invented;
- *rationalization*, in which plausible but false justifications or excuses are used to explain an unpleasant truth; and
- *projective identification*, in which aspects of the self are projected onto another or others. The other accepts the projection and acts accordingly.

Childhood Experiences Influence Adult Personality

Longitudinal research examining personality has found that, in the absence of significant environmental stressors, individuals develop ego capacity to tolerate and resolve intrapsychic conflict relatively effectively and that this development continues over the life span. That is, childhood experiences can predict both psychopathology and psychological health. This tenet corresponds significantly with the tenet of developmental trajectory (see section Trajectory of Maturation later in this entry).

Early psychoanalytic theorists hypothesized that primitive drives such as sex and aggression were the primary motivators for human behavior. However, subsequent research has shown that, in general, the urge to affiliate is one of the primary motivators in humans. The capacity for attachment is influenced by experiences in childhood. Childhood trauma such as childhood abuse (emotional, physical, and/or sexual), neglect, and/or instability in the family environment (e.g., parental substance abuse, domestic violence, other criminal behavior) predicts psychopathology including antisocial personality disorder and borderline personality disorder. These personality disorders are overrepresented among criminals.

Developments in 20th-century psychoanalytic research found that, in the absence of developmental trauma or primary psychopathy, individuals would maximize their capacity to love and work.

The findings of higher rates of childhood trauma among prisoners support this hypothesis.

Mental Representations of Self, Other, and Relationships Influence Psychological Symptoms

Mental representations are relatively stable images of things one has experienced. These things include the self, others, and relationships. Other psychological theories have similar concepts referred to as *schemas* or *constructs* but without the assumption of unconscious mental processing.

When self-representations are negative, anxious and depressive symptoms may result. The self is experienced as inadequate to meet the demands of life. When mental representations of others are negative, suspicion, anger, or fear may result. Others are perceived as at best inadequate and at worst hostile. Mental representations of relationships are involved in the psychoanalytic concept of transference (*übertragung*) and countertransference (*Gegenübertragung*). Transference occurs when the patient transfers old relationship representations onto the therapist; countertransference occurs when the therapist transfers onto the patient. Transference also occurs in relationships outside therapy but is discussed less in the psychoanalytic literature. Problems arise when one transfers a dysfunctional relationship pattern onto a relatively healthy relationship. For example, individuals with a significant history of abuse by authority figures experience their supervisor as sadistic and aggressive and take measures to protect themselves despite the fact that the supervisor has only met them once and did not act aggressively.

In the 1990s, psychodynamic researchers Reid Meloy and Carl Gacono studied mental representations of prisoners. Their findings were consistent with the theory in that prisoners with antisocial, narcissistic, and/or borderline features tended to have dysfunctional mental representations of themselves (e.g., grandiose), others (e.g., devalued, split, projected onto), and relationships (e.g., deficient attachment).

Trajectory of Maturation

Freud's psychosexual developmental theory held that individuals develop through specific stages in infancy and childhood, during which gratification

is focused on specific body parts. Infants are gratified through the mouth (e.g., feeding) during the oral stage; this stage is characterized by passivity and dependency. Toddlers are gratified by controlling their bowel movement during the anal stage; this stage is characterized by a desire for control and order. Young children (boys) are gratified through the penis during the phallic stage. The Oedipus complex occurs during this stage, in which the child learns social rules that may conflict with his wishes and emotions. Middle childhood is characterized by psychosexual latency; there is no specific focus of gratification, and the child focuses on building skills. Late childhood/early adolescence is characterized by gratification through the sexual organs, and the genital stage lasts through adulthood.

Freud theorized that successful transition through the psychosexual stages leads to an adaptive relatively conflict-free personality capable of loving and working and that unsuccessful resolution of a stage (e.g., due to psychological trauma occurring during the stage that diverted attention from its resolution) left one *fixated*. For example, an orally fixated personality would be dependent and passive. An anally fixated personality would be characterized by themes of control. Although Freud's psychosexual stage theory did not stand up to empirical research, in that the symptoms he described in adults have not been linked to psychological trauma in childhood in the ways he theorized, the patterns he described have been observed and there are consistent findings that childhood experiences affect adult personality.

Psychoanalytic developmental theory that has been supported by research includes the observation that maladaptive (or immature) defenses are the first to develop. These include splitting, acting out, and projection. The capacity for more adaptive defense mechanisms emerges later in childhood. Other capacities that develop include increasingly complex interpersonal relationships, growth in one's capacity to take the perspective of others, greater investment in others for their internal qualities rather than material qualities or what they can provide one, and an increased capacity to put moral values above immediate emotions.

Crime is not different from other ineffective or immature behavior in that it often involves the direct expression of unconscious impulses. Since by adulthood most individuals develop a more

effective capacity for emotional regulation, attachment, and compromise formation, one conclusion is that individuals repeatedly involved in crime have had blocks to their psychological maturation. Findings in defense mechanism research support this hypothesis, as criminals tend to use more immature or maladaptive defenses than nonclinical samples.

PSYCHODIAGNOSTIC INTERVIEW

The psychodiagnostic interview is an essential component of mental health diagnosis in which mental health professionals collect specific information about an individual to label his or her mental health problems. A significant number of individuals involved in the criminal justice system have been diagnosed with a mental disorder. Many more may have undiagnosed problems. Misdiagnosed or undiagnosed problems pose a serious barrier to the rehabilitation of offenders as

accurate diagnosis is an important early step to effective treatment. There is ongoing concern that untreated mental disorders may lead to violence or reoffense. This entry introduces readers to the goals of psychodiagnostic interviewing, offers examples of different approaches to interviewing, and provides a brief overview of the key content covered in a typical interview.

Interview Goals

The goal of a psychodiagnostic interview appears clear: to diagnose a mental disorder. Yet, there remains debate about the best way to conceptualize mental disorders. The most commonly used system in the United States is described in the *Diagnostic and Statistical Manual of Mental Disorders (DSM)*, published by the American Psychiatric Association. Much of the rest of the world uses the *International Classification of Diseases*, published by the World Health Organization. Both of these are categorical classification systems in which each disorder is seen as a distinct collection of various symptoms. A threshold number of symptoms are typically required for each disorder, and an interviewer needs to assess for all possible symptoms, along with specific information on the length of time symptoms have been present and other possible explanations for them. For example, to diagnose a form of depression called *major depressive disorder* using the *DSM*, an interviewer would ask questions about nine specific symptoms outlined in the manual. The presence of five of these over at least a 2-week period qualifies for the diagnosis. The interviewer must also inquire about other possible explanations for any symptoms reported such as a medical problem or bereavement. This approach to diagnosis is not without limitations. Chiefly, categorical diagnosis allows for only two possibilities: One either has the disorder or one does not. Some people may be experiencing significant distress or impairment in functioning but not reach the number of symptoms specified or time requirements. In addition, symptoms of some disorders overlap, and interviewers may struggle to decide whether an interviewee's report of problems with excess energy is evidence of a condition such as bipolar disorder, severe attention-deficit/hyperactivity disorder, or behaviors associated with substance abuse and/or

antisocial personality disorder. Thorough interviewing can help sort through some of these challenges, but they may also reflect inherent weaknesses to a categorical approach to diagnostic classification.

In response to these concerns, it has been suggested that a better way to think about mental disorders is as symptoms that present on a continuum often with normal functioning. In this approach, what distinguishes symptoms of mental disorder from normal functioning is the severity of the problem. Rather than asking questions to *fit* a person into a specific category, an interviewer might instead seek to gather information about an individual's overall level of functioning and place specific symptoms reported into larger factors. At the broadest level, *internalizing disorders* are those that generally involve emotional distress, whereas *externalizing disorders* involve problems with behavior or impulse control. Given the goal of locating an interviewee's problems on a continuum, interviewers would likely supplement information they obtain from the individual with norm-referenced assessment measures that compare an individual's symptoms to a comparison group.

While conceptual debates about the classification of mental disorders are likely to continue, as of 2018, the approach to diagnosis required by third parties such as health insurance companies remains the categorical one. The goals of mental health assessments conducted for the legal system vary, and interviewers must determine the specific nature of the question they are being asked to answer to appropriately focus their interview questions. Evaluations of claims of legal insanity often hinge on the presence of a recognized *DSM* or *International Classification of Diseases* mental disorder, for example, evaluating competency to stand trial may require no diagnosis at all and focus instead on a defendant's dimensionally assessed functional capacity to understand legal concepts and assist in his or her defense.

Approaches to Psychodiagnostic Interviewing

Two main approaches to psychodiagnostic interviewing include unstructured clinical and structured interviews. Unstructured clinical interviews

resemble a traditional dialogue between the interviewer and interviewee. While each interviewer may develop his or her own preferred phrasing or order of questions, the clinical interview allows for spontaneity, and the specific questions asked may vary from interview to interview (though the general content covered should be the same as discussed in the following section). Structured interviews, on the other hand, involve specific questions posed to each interviewee in the same way. Some structured interviews may be referred to as *semistructured*. These standardized guides to data collection ensure that all areas of importance are covered while allowing the interviewer to customize questions based on an interviewee's answers and/or ask additional questions deemed appropriate. Examples of structured interviews include the Structured Clinical Interview for DSM Disorders and the Diagnostic Interview Schedule.

Therapists often prefer clinical interviews and the personalized approach they provide while researchers typically use structured interviews to gather standardized data. Psychodiagnostic interviews completed for the legal system may use either depending on the specific question being asked.

Interview Content

Informed Consent and Establishing Rapport

A psychodiagnostic interview requires both consent and cooperation. This consent is generally described as *informed consent* and requires the interviewer to explain the purpose, time requirements, and any limits to confidentiality, among other things. Given that interviews completed for the legal system typically offer little to no confidentiality, interviewees may be understandably reluctant to participate or reticent about their thoughts and feelings. Thus, while developing treatment plans may or may not be the goal of the interview, skilled forensic interviewers must balance objectivity with empathy and positive regard for the interviewee to gain cooperation. Interviewers must also be prepared to take steps to protect the interviewee or the community from harm, should a significant risk of suicide or violence emerge during the interview regardless of its purpose.

Behavioral Observations

A psychodiagnostic interview may actually start before a single question is posed, as the diagnosis of a mental disorder entails consideration of both information reported by an individual and observations made by the diagnostician. *Symptoms* are problematic thoughts, feelings, and behaviors an interviewee endorses. They are subjective. *Signs* are objective observations that have diagnostic meaning. For example, recurrent thoughts of death or suicide are a symptom of major depressive disorder one can only assess by explicitly asking about them. Excessive slowing of speech or movements known as *psychomotor retardation* is a sign of the disorder that can be observed by the interviewer. An interviewer generally takes note of an individual's general appearance, activity level, speech patterns, and emotional expressiveness. Unusual behaviors or mannerisms may also be particularly important to identify.

Presenting Problem or Reason for Referral

Individuals who voluntarily seek assessment and treatment are usually able to clearly identify a problem for which they are seeking assistance (e.g., depression). The interviewer will question the nature of the problem, when it started, and for how long it has persisted to determine whether it meets criteria for a diagnosis like major depressive disorder. Those completing a psychodiagnostic interview as part of a court process or within a correctional setting may be less articulate and/or less forthcoming such that they may not endorse any problems at all. In such cases, information from the legal system may be particularly important, and the individual can be queried as to his or her perception for the reason for the referral (e.g., "What is your understanding of why you are here today?"). Discrepancies between the information provided by the court system and the individual's account may speak to one's level of insight into the problem, particularly if care has been taken to establish rapport, and it is believed the individual is honestly answering interview questions.

Current Functioning and Distress

After clarification of the presenting problem or reason for referral, most psychodiagnostic

interviewers will complete a survey of the individual's psychological functioning. Major areas to be considered include mood and emotional regulation, concentration and/or memory problems, and impulse control. In addition to current mood, the interviewee is asked about his or her *regular* mood and any periods of persistently negative mood or significant changes in any direction. Psychodiagnostic interviewers often find it helpful to ask whether others have ever told the individual that he or she seems different in some way as some features of certain mental disorders may not actually feel like a problem to the individual (e.g., manic episodes marked by euphoria in an individual with bipolar disorder, interpersonal difficulties in a person with antisocial personality disorder). The interviewee's sleep patterns, current substance use, and general health are also typically explored.

Investigation of an individual's social network and interpersonal functioning is also important. Interviewers ask about performance at school or work as well, particularly in relation to any significant problems with the aforementioned psychological issues. This is necessary as the diagnosis of mental health disorders with a system such as the *DSM* requires evidence of significant distress or impairment in functioning related to symptoms.

History

Accurate diagnosis puts the presenting problem and current functioning in context. As such, taking a thorough history of the individual's psychological functioning is necessary. Major areas to consider are the interviewee's developmental, social, legal, academic/work, medical, and substance use history. Children and adolescents are sometimes known to be poor historians, and this may be an area in which more information can be gleaned from parents. Adults may also struggle to recall aspects of their history (which may valuable information in and of itself). Any gaps in knowledge that could impact the ultimate diagnosis should attempt to be clarified. Some diagnoses may actually require historical information (e.g., the *DSM* diagnosis of antisocial personality disorder in adults requires evidence of conduct disorder before age 15 years). If significant gaps in history remain even after thorough interviewing, some

degree of diagnostic uncertainty will be present and should be communicated to the interviewee or referral source.

Mental Status Examination and Risk Assessment

At this point, much data will have been covered, and clear risk issues may have emerged in the interview if the individual reported past suicidal thoughts or behavior or the reason for referral was a threat or past act of violence. All psychodiagnostic interviews should consider risk of harm to self or others. If this has not been covered in an earlier part of the interview, it will be in the mental status examination. The mental status examination involves consideration of the observations made of the individual along with specific questions about his or her current mood, perceptual experiences (i.e., hallucinations), and thought content (i.e., delusions, suicidal ideation, and homicidal or violent ideation). Suicide is associated with multiple mental health disorders and should not only be considered a possibility if the person appears *depressed*. Violent behavior shares a more complicated relationship with mental disorders but is also to be routinely assessed. Regardless of the interview context, mental health professionals have an ethical duty to protect others from harm and may have a legal duty to do so as well.

Final Thoughts

Effective rehabilitation of criminal offenders and/or prevention of criminal behavior may often depend on an accurate mental health diagnosis. Although there is some debate about the nature of mental health disorders and the best way to classify them, accurate diagnosis with current diagnostic systems always requires a comprehensive psychodiagnostic interview by an interviewer who keenly observes an individual's behavior and systematically collects information from the individual in the areas reviewed herein.

PSYCHOLOGICAL AUTOPSY

Psychological autopsy is a generic term used to describe a form of psychological assessment undertaken in a postmortem and postdictive capacity for determining various attributes in a person who is deceased. The goal and thus purpose of undertaking a psychological autopsy varies and is largely dependent on the circumstance in which the evaluation is being undertaken. In this respect, there are generally three broad contexts wherein psychological autopsies are used. The first is within the framework of an investigation into the death of an individual that has occurred in indeterminate and thus equivocal circumstances such as those undertaken by coroners. In this context, the purpose of a psychological autopsy is to assist in determining whether the deceased person's demise was most likely due to natural causes, some form of accident, a suicide, or a possible homicide. The second context is within the framework of a police operation whereby an understanding of a deceased person might assist with some ongoing or ancillary aspect of the police investigation. An illustration of this circumstance

is the use of a psychological autopsy to obtain some understanding of a deceased offender's mental state and thus likely motive for perpetrating a mass shooting before the offender was killed by responding police or security personnel. The third context is within a therapeutic setting such as a hospital or psychiatric facility or some form of research concerned with the treatment and/or study of the etiology and predisposing factors associated with suicide. An example illustrating the use of psychological autopsy in this context is an evaluation of a patient who has committed suicide and the factors which led to the patient's death. With this information, treatment regimens can be improved upon in the future.

Although these contextual frameworks for undertaking a psychological autopsy differ, the underlying functional theme to the analysis of a deceased person is generally the same, and thus, in many respects, the functional outcome of a psychological autopsy is analogous to the reconstructive task undertaken by biographers and historians when they consider the likely sentiments and disposition of a historical figure.

The Process for Undertaking a Psychological Autopsy

Although the psychological autopsy technique has achieved considerable professional recognition in terms of its acceptance and widespread use in many operational environments (e.g., law enforcement, coronial inquiries), it does not feature a uniformly recognized procedure concerning how precisely the technique is undertaken. Many of the variations in procedure for the technique appear to be nuances and artifacts of the disciplinary background of the individuals who are undertaking the analysis. For example, individuals from legal or law enforcement backgrounds typically place greater emphasis upon the analysis of tangible evidence, whereas individuals from mental health disciplinary backgrounds tend to be more orientated to evaluating motivational drives and possible psychopathologies.

Despite these different disciplinary perspectives and points of emphasis, there are, nonetheless, a number of underlying procedural commonalities that all approaches share. The most fundamental is that all approaches commence with an

information collation process wherein a myriad of data sources connected with the deceased are consulted. Examples of such sources include reviewing archival records (e.g., medical records, educational records, police records) as well as conducting interviews with family members, friends of the deceased, and any other relevant parties (e.g., treating doctors) who may have been in a position to offer some insight into the disposition of the deceased prior to their death.

Following this data collection phase, the next frequent step is a preliminary analysis of core attributes concerning the deceased. From this initial analysis, a composite of many descriptive features concerning the deceased is developed, which leads to some preliminary conclusions such as the deceased's likely mental state and overall well-being prior to his or her death. In addition, some impression of the deceased's life history as well as any significant life events and stressors that may have been in operation prior to the individual's demise is developed.

The final common procedural component to the composition of a psychological autopsy typically involves a more focused analysis of the deceased. At this stage, the operational context of the psychological autopsy is a key factor in shaping the questions which the psychological autopsy seeks to determine. For example, within the aforementioned context of a coronial inquiry, there is some consideration of the likely intentions of the deceased and thus some assessment as to whether his or her death was in some context intentional or unintentional. Likewise, within the previous example concerning a law enforcement investigation of a shooting spree, the questions under consideration might revolve around whether the deceased harbored any prejudicial views or held any radical political beliefs that might suggest his or her actions was an expression of a hate crime versus an act of political violence (e.g., terrorism).

With respect to the matter of method, there does not appear to be any clear consensus as to whether psychological autopsies are optimally undertaken by a single person or via the efforts of multiple analysts collectively working together. There are favorable and unfavorable aspects to both approaches. Psychological autopsies undertaken by a single person are believed to facilitate a better level of perspicuity via the expertise of the

analyst. In this context, all collected information and conducted interviews have been undertaken by a single person who has a better overall understanding of all the gathered information. However, many of the methodological problems inherent to psychological autopsy (examined in the following section) arise within this single analyst/practitioner operating model. In contrast, a psychological autopsy undertaken via a team effort involving multiple analysts who collectively work together may be more robust and thus not as prone to such problems surrounding the reliability of psychological autopsies. However, through this team approach, diffusion of the collected information can also occur, and thus, the perspicuity and level of insights garnered from such analysis may suffer via this approach.

Limitations

Despite the touted benefits derived from the use of psychological autopsies, the technique itself is hindered by a number of methodological limitations and one irreconcilable issue concerning its validity. With respect to methodological limitations, there are numerous issues concerning the reliability of the collected information upon which any evaluation is founded. These limitations feature two dimensions in terms of the reliability of the supplied information as well as how the collated information is subsequently interpreted.

With respect to the reliability of the collated information, there are numerous hazards associated with the accounts family members and friends of the deceased may supply. Ironically, the unreliability of such information can be quite polarized in nature wherein descriptions of a deceased individual may be grossly exaggerated in either an extremely favorable or unfavorable manner. For example, when asked to recollect aspects of the deceased's life, bereaving family members can romanticize their recollections and thus consciously or even subconsciously deny or downplay patently evident issues connotative of dysfunction within the life of the deceased person. Alternatively, when the circumstances of a deceased individual's death are considered to be the source of some form of great shame that subsequently extends to the surviving family members, recollections may grossly misrepresent any anomaly. That

is, the exaggeration of any dysfunction may act as a means of quarantining surviving family members or significant others from any perceived stigma and disgrace caused by the deceased individual.

To address these problems, various methodological procedures that attempt to buttress the overall reliability of the evaluative process for the purpose of a psychological autopsy have been suggested. Some simple mechanisms involve the corroboration of information from multiple differing sources. However, more sophisticated protocols involve structured interviews that are conducted at differing time intervals (when permissible), whereby any manifest grief in, for example, a relative may have dissipated.

The problems surrounding the reliability of information used for psychological autopsies also extend to the personnel who may be undertaking the analysis. That is, during the course of conducting interviews with bereaving family members and friends, a degree of empathy and thus sympathy can readily develop, which can thereafter skew the objectivity of the conclusions formulated within a psychological autopsy. To counteract this problem, a number of contingencies have been proposed. One is having separate individuals conducting interviews with those who thereafter use the obtained information for analysis incumbent to the psychological autopsy. Another strategy involves the overall analysis for a psychological autopsy being undertaken by a group of analysts whereby any determinations are made via a process of consensus.

Despite these limitations and their various countermeasures, the psychological autopsy technique suffers from one irreconcilable issue concerning its validity. The simple fact is that there is no way in which some of the key conclusions inherent to psychological autopsies can be unequivocally and empirically verified as accurate and thus valid. That is, it is impossible to definitively ascertain whether any espoused conclusions surrounding the motives and intentions of the deceased are indeed correct, because the only individual who could confirm the validity of these conclusions is the deceased. Thus, the validity of the psychological autopsy technique is a matter of stringency in perspective somewhat analogous to the standards of proof encountered in legal forums generally. In many civil law contexts, the standard

of proof is based upon the balance of probabilities as to what is most likely the case, whereas in criminal law, the standard is far more stringent and based upon the belief that determinations must be beyond a reasonable doubt. In an analogous context, the validity of psychological autopsies is a matter of perspective in determining whether the conclusions are highly probable as being valid or whether a definitive standard must be met consistent with some independent metric for verification.

Psychological Autopsies as Evidence in Court Proceedings

Despite the aforementioned limitations, the psychological autopsy technique enjoys a somewhat paradoxical status when considered as a form of expert witness evidence for legal proceedings. In jurisdictions outside the United States, such as, for example, the United Kingdom and Canada, the submission of evidence in the nature of psychological autopsy has been largely rejected irrespective of whether it is tendered in civil or criminal proceedings. The overall reason for this rejection has been the lack of scientific research capable of robustly substantiating its validity and thus any testimony derived from its premises.

In stark contrast to this position, the psychological autopsy technique has been regarded as an admissible form of expert witness evidence in many jurisdictions in the United States. Indeed, in the United States, the admission of evidence in the nature of psychological autopsy dates back to the 1930s. In this respect, the applications of psychological autopsy as legal evidence are quite diverse and include applications of the technique to legal proceedings concerning medical malpractice and insurance and workers' compensation claims. However, this acceptance of psychological autopsy as evidence is not unilateral; thus, in some civil law contexts, it is regarded as inadmissible, such as in matters pertaining to intestate succession and testamentary capacity. Moreover, within the context of criminal law, the admissibility of psychological autopsy is quite divided in terms of it being accepted in some jurisdictions but not others; thus, its admission within criminal proceedings is heavily dependent on the specific parameters of the issues to be determined before the court and the extent to

which psychological autopsy is exclusively meant to be relied upon in making such determinations.

PSYCHOLOGY OF CRIMINAL CONDUCT

The *Psychology of Criminal Conduct* (PCC) is both a title to a book by James Bonta and Donald A. Andrews (in its sixth edition as of 2017) and a perspective on criminal behavior. PCC is most importantly a psychological and an evidence-informed understanding of criminal conduct that sets itself apart from traditional criminological and mental health explanations of criminal behavior. Until the publication of the first edition of the *Psychology of Criminal Conduct* in 1994, traditional mainstream criminology emphasized the importance of a person's position in the socioeconomic structure of society. That is, the cause of crime was to be found in external, social forces that maintained individuals in a disadvantaged position (e.g., poverty, racial

bias). Mental health explanations, on the contrary, locate the cause within the person, and the causes are often found to be psychopathological. PCC is a perspective of crime that includes aspects of criminological and mental health theories with an emphasis on understanding the criminal behavior of individuals within a social, personality, and cognitive context of action. It seeks an explanation of interindividual (between persons) and intraindividual (within a person over time and space) variations in behavior. That is, it asks why some people commit crime more frequently and seriously than others, and why some commit crime at a certain point in time and in specific situations and not at another time or in another situation. The answers to these questions are informed by a general personality and cognitive social learning (GPCSL) theory of criminal conduct. What sets PCC apart from many other perspectives of crime is that it specifies how criminal behavior is learned and outlines a model for assessing and treating offenders. This entry discusses the major principles of learning, the importance of the person-based factors of procriminal attitudes and antisocial personality within the social context, and the Risk-Need-Responsivity (RNR) model of offender assessment and treatment.

Learning Criminal Behavior

GPCSL makes a number of assumptions. First, criminal behavior is learned according to the same processes that determine the learning of any behavior. This means that criminal behavior is governed by the principles of vicarious learning (modeling), operant conditioning (the influence of consequent rewards and costs/punishment), and classical conditioning (antecedent stimuli gaining control over behavior). It also means that GPCSL is a general, encompassing perspective of criminal behavior. There is no need for theories of white-collar crime, sex offenders, or other criminal subgroups. All that is required to understand these subgroups is to make adjustments to the general constructs (e.g., for sex offenders one would investigate attitudes specific to sexual offending rather than general procriminal attitudes). Second, the processes of learning interact with the personality and cognitive characteristics of the individual. Third, learning occurs within a social context.

Because individuals vary in their personal characteristics and find themselves in different situations, the route to criminal behavior is varied. Offenders may have many similarities but they also differ.

In general psychology, the learning principles have been extensively studied and are now well established. Few would reject the idea that behavior is learned from watching others, from being encouraged or punished for certain actions, or that individuals may acquire almost automatic reactions to stimuli through association with other stimuli (e.g., feelings of anxiety at the sight of a needle). The learning of behavior depends upon the reward and cost contingencies for a specific behavior (PCC purposely uses the term *costs* instead of *punishment* to avoid some of the complexities and misunderstandings that surround the latter). Criminal behavior, as is true with any behavior, is under the control of signaled rewards and costs that come prior to the behavior and rewards and costs that follow the behavior. Antecedent rewards or costs can be models that signal to the person that, if one imitates the behavior, rewards or costs will follow. In classical conditioning, the stimulus may trigger certain reactions that have been associated with a reward or cost. For example, a prior traumatic experience may lead to an emotional reaction in a similar situation. The source of rewards and costs can be interpersonal, personal (one's own thoughts), and automatic.

An important concept in the learning of behavior is density. GPCSL uses the term *density* to simplify what learning psychologists call *schedules of reinforcement/punishment*. Schedules refer to the arrangement of rewards and costs based upon the interval between the behavior and the reward or cost (e.g., experiencing a hangover in the morning after a night of heavy drinking) or the ratio between the number of times the behavior must occur before a reward or cost follows (e.g., trying to open five car doors before finding an unlocked door). Schedules can be further detailed into fixed and variable schedules. Density refers to the variety, immediacy, magnitude, and frequency of signaled (antecedent) and consequent rewards or costs. In GPCSL, there are two important points. First, the density of rewards or costs operates on both criminal and prosocial behavior. This means that whenever rewards or costs are altered for criminal behavior, it will also impact on prosocial behavior. For example, if

criminal behavior becomes more rewarding, then the costs for prosocial behavior increase.

A second important point is that the impact of a reward or cost depends on the extant rewards or costs associated with the behavior. This impact will be greatest when the background density of rewards or costs is at an intermediate level. The introduction of a new reward or cost will have a minimal effect when the background density of rewards or costs is at the extreme. For example, threatening a very successful criminal who has a high background density of rewards for crime with an extra 30 days in jail is unlikely to alter his or her antisocial activity. Similarly, threatening jail for a very prosocial individual is unnecessary since criminal behavior already has a high background density of costs (e.g., loss of employment, freedom, respect of friends and family). One cannot understand how a new reward or cost can change behavior without understanding the rewards or costs that are already in operation.

Just as one must appreciate the role of the background density of rewards or costs, one must also understand how the learning processes interact with state, personality, intellectual, and cognitive factors. The impact of a reward or cost varies with the person's state (e.g., expressing disapproval may be more meaningful when the person is sober rather than intoxicated). Personality characteristics may interact with rewards or costs (e.g., offering a hug to a severely depressed individual would have a different impact than to a paranoid and anxious individual). Finally, intellectual-cognitive factors can moderate the influence of rewards or costs (e.g., a candy bar is more likely to elicit a desired behavior from a 2-year-old than offering US\$10).

Personality

Criminal behavior is learned in interaction with biosocial personality factors conducive to antisocial acts. From a GPCSL perspective, the following two personal factors are given prominence: procriminal attitudes and antisocial personality pattern (APP). *Procriminal attitudes* are thoughts, feelings, and beliefs that are supportive of criminal conduct (that it is justifiable to break the law). In PCC, there are three general categories of procriminal attitudes: (1) techniques of neutralization, (2) identification with criminal others, and

(3) rejection of convention. All the three types of procriminal attitudes make it personally easier to engage in criminal behavior.

Techniques of neutralization begin with the idea that most offenders know that their actions are wrong. That is, criminal behavior is not simply a failure in moral development. Knowing that antisocial behavior is condemned by society, and perhaps even that he or she will feel guilt and shame, the offender attempts to neutralize the potential punishment associated with the antisocial behavior. Offenders may engage certain cognitions that avoid or minimize punishment from others and themselves. For example, an offender may minimize the harm to the victim (e.g., "I was going to return the car after my ride") or justify the behavior by an appeal to a higher loyalty (e.g., "I had to steal to feed my family"). Sometimes, the legal system facilitates neutralizations when mitigating factors are applied in sentencing decisions (e.g., "He was too drunk to be fully responsible for his behavior," "Her abusive past led her into prostitution").

The second category of procriminal attitudes is identification with criminal others. It is not about how to excuse or minimize the criminal behavior, but it is actual approval and pride in antisocial behavior. These attitudes give positive evaluations to criminal behavior and criminal others. Being criminal is valued (e.g., "I am tough"), and identifying with other offenders is a source of pride (e.g., "He is part of my family"). Finally, there is rejection of convention. Social institutions (e.g., work, education, the legal system) that are meant to socialize individuals into a prosocial lifestyle are rejected. Thus, by minimizing their reward value, not only are the motives for prosocial behavior lessened (e.g., "I can make more money selling drugs than working in a factory"), but crime itself becomes less costly (e.g., "It doesn't matter if I lose my job").

Procriminal attitudes are central to most theories of criminal behavior, and in GPCSL, they are essential. Procriminal attitudes not only represent one of the major correlates of criminal conduct but also are fundamental to the control of criminal behavior. Unlike other factors associated with criminal conduct, such as procriminal companions and substance abuse, attitudes and cognitions are most proximal in time to the behavior and completely under the individual's control. Immediately prior to the behavior comes cognitions that

evaluate the favorableness of the action (i.e., the likelihood of rewards or costs). Having procriminal attitudes and thoughts increases the chances of criminal behavior. From a treatment perspective, if procriminal attitudes can be replaced with prosocial attitudes, then the probability of criminal behavior is diminished. Within GPCSL, thoughts and attitudes are under personal control, and therefore, PCC assigns personal agency to the individual.

APP describes the impulsive, adventurous, pleasure-seeking individual who is constantly in trouble, often aggressive, and who shows a callous disregard for others. The origins of APP are in a difficult temperament characterized by poor self-control and negative emotionality. These personality characteristics, not surprisingly, predispose the person to problematic relationships in a variety of settings. For example, impulsivity may lead to difficulties in the areas of education and employment, and adventurous risk-taking and pleasure-seeking are fulfilled by criminal activity.

It is important to note that in PCC, APP is not antisocial personality disorder as described in the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition*, nor is it psychopathy as measured by instruments such as the Psychopathy Checklist-Revised. PCC's definition of APP includes both personality and behavioral characteristics that are relevant to the assessment and treatment of criminal behavior. The word *pattern* signifies personality traits (e.g., impulsiveness, sensation-seeking, egocentrism, hostile emotions, and attitudes) and a pattern of law-violating and problematic behaviors. Unlike Travis Hirschi's theory of self-control, whereby low self-control is sufficient to explain criminal behavior, PCC's APP goes beyond self-control to explain criminal conduct.

The Social Context

Learning occurs within a variety of social contexts. In PCC, the major social environments where learning occurs are education/employment, family/marital, leisure/recreation, companions, and, within a subset of companions, substance abuse. The five groupings are part of the central eight risk/need factors described by PCC. The other three major risk/need correlates of criminal conduct are criminal history, procriminal attitudes, and APP. Together,

they represent the best predictors, and potentially the best causal factors, of criminal behavior.

Education and employment are learning environments that society structures to socialize individuals to become productive, prosocial citizens. Within these social contexts, rewards are given for specific prosocial behaviors such as doing homework, obtaining good grades, reporting to work on time, and being productive on the job. Costs also are provided for failure to meet the behavioral expectations demanded by these environments. Obviously, a high density of rewards and a low density of costs will ensure involvement in educational and work-related behaviors. However, this also impacts on the likelihood of criminal behavior. An individual who receives many rewards for his or her behavior from teachers, employers, fellow students, and coworkers, and if the activity itself is rewarding, then that person has a great deal to lose for engaging in crime. Many offenders who have done poorly in school and who are unemployed or in jobs that they do not like will receive few rewards for prosocial behavior. They also have less to lose for criminal behavior.

The family/marital situation is interesting because both the origins and maintenance of criminal conduct are found within this social context. With respect to origins, the parent is usually the primary socializing agent for children. Putting aside the influence of heredity, parents who are either clearly procriminal themselves or who cannot recognize and properly deal with antisocial behavior by their children shape future delinquent behavior. The parent may model inappropriate behavior (signaled rewards), reward aggression, and fail to properly discipline noncompliance to social norms. In adulthood, criminal behavior may be maintained by the reciprocal reinforcement of the behavior by a procriminal couple (offenders tend to form romantic relationships with similar partners, called *assortative mating*). Also, in the situation where one or both partners are prosocial but have little investment in the relationship, the costs (losing the love and respect of the partner) for deviance are low.

Leisure/recreation describes activities outside the aforementioned social contexts. They vary from organized recreational sports, church attendance, to even regular attendance at Alcoholics

Anonymous meetings. Participating in these activities can be an important interpersonal and personal source of rewards for prosocial behavior. Enjoyment (rewards) can come from a variety of prosocial others (e.g., baseball coach, Alcoholics Anonymous sponsor) and from the behavior itself (e.g., pride in winning a game, feeling of personal fulfillment from spiritual contemplation). A lack of participation in prosocial leisure/recreational activities, a common characteristic of offenders, leaves more time for criminal activities and a loss of opportunity for receiving rewards for prosocial behavior. Furthermore, there are few people to deliver costs for antisocial behavior.

One of the most empirically replicated and theoretically relevant risk factors for criminal behavior is companions. Social interactions among friends and associates provide an interchange of rewards and costs for prosocial and procriminal behaviors. Research has demonstrated that delinquent groups express approval for criminal behavior and disapproval for prosocial behavior. Similarly, prosocial companions reward prosocial behaviors and deliver costs to criminal behavior. High-quality relationships within either group can exert powerful control over behavior because respect, warmth, and care enhance the magnitude of the reward/cost (recall magnitude is related to the density of rewards/costs).

Finally, substance abuse influences criminal behavior through two mechanisms. Ingesting drugs and/or alcohol can produce automatic rewards. For example, snorting cocaine produces feelings of euphoria, and having a drink in the morning may mitigate the effects of a hangover. As important as these immediate rewards are to behavior, for most offenders, misusing drugs and alcohol usually occurs in a social situation, with companions. In the case of illegal drugs, one must also interact with other offenders in order to obtain drugs, thereby opening oneself up to the influence of criminal companions. In the case of alcohol, behavior may be disinhibited, but without the support of criminal others antisocial acts do not necessarily follow (there are many alcoholics with no criminal record). All told, within the social context surrounding substance abuse, there is tremendous interpersonal encouragement to take drugs and/or drink excessively.

An important implication from PCC's concept of the central eight risk/need factors is that not all offenders have difficulties with each of the factors. Some may have substance abuse issues along with problems in employment. Others may have difficulties at home and have procriminal attitudes, along with strong ties to other criminals. They are all engaging in criminal behavior but for different reasons. The route to criminal behavior is complex and varied.

The Situation of Action

The discussion of personality and the social context explains interindividual differences. Some individuals are more likely to engage in crime than others because they have APP, procriminal attitudes, substance abuse problems, and difficulties with employment. In general, as the number of central eight risk/need factors increase, so too does the risk of criminal behavior. These factors also go a long way in explaining intraindividual differences. The more central eight factors, the more likely that the individual will behave antisocially over time and across a variety of situations. However, casual observation of offenders find that even the highest-risk offender can behave in a prosocial manner. Every situation of behavioral action has its own reward/cost structure. Thus, for example, the presence of a police officer may inhibit criminal behavior, while an unoccupied house with the door open may facilitate a criminal act.

One may think of the central eight as the major factors that predispose the person to criminal behavior. Their establishment takes time to develop. For example, one does not suddenly make procriminal friends. It can start in early childhood where parents fail to properly monitor and discipline the child, school problems lead to rejection from prosocial children, and taking drugs exposes one to procriminal others. The specific expression of criminal behavior is dependent on the reward/cost contingencies in the situation of action. The individual analyzes the signaled rewards (e.g., open door to house) and signaled costs (e.g., no police present) and then acts on his or her criminal predisposition.

The Applied Value of PCC

PCC is intended to make theoretical sense and to have the support of evidence. A third goal of

PCC is that it should have practical value. As described earlier, PCC identifies the central eight risk/need factors that should form the basis of offender assessment instruments. The central eight, along with an understanding of learning principles, also informs effective offender treatment programs. GPCSL does this through the RNR model. The RNR model was first formulated in 1990 with four important clinical principles. The *risk principle* states that the intensity of treatment services should be matched to the risk level of the offender, with low-risk offenders receiving minimal treatment services and high-risk offenders receiving the most treatment. The *need principle* calls for the assessment and targeting of the criminogenic needs of offenders in treatment (i.e., the central eight minus criminal history which is a static, unmodifiable risk factor). The *responsivity principle* advises using cognitive behavioral techniques to deliver treatment and to be attentive to the individual's motivation and learning style. The last principle, *professional override*, allows the professional to exercise judgment in those situations where the RNR principles do not fully inform the understanding of the individual.

Since 1990, the RNR model has been expanded to 15 principles, to include the overarching principles of respect for the person and the prevention of crime through service delivery that is based on GPCSL. In addition, a set of organizational principles highlights the importance of management selecting and training staff in GPCSL-based practices with a focus of delivering services in the community where the reductions in recidivism are greater. RNR programming can work in custodial and residential settings, but their impact on recidivism is approximately half that of services delivered in the community. Although the expanded RNR model now has 15 principles, the four clinical principles described remain at the core of the RNR model.

The first major area of application of the PCC perspective is the assessment of offenders. According to PCC, the assessment should be structured and include measuring the central eight risk/need factors. However, RNR assessment is not only risk oriented but also problem oriented. Personal strengths are also assessed, along with responsivity factors, since both play an important role in the treatment of offenders. PCC recognizes that although offenders have many common attributes,

any particular offender may find himself or herself in unique circumstances. Therefore, the RNR model permits the exercise of professional discretion. A good example of a structured offender assessment instrument that is RNR-based is the Level of Service/Case Management Inventory. This instrument assesses overall risk to reoffend, the individual's criminogenic needs (i.e., the central eight), and responsivity factors.

The second area of application is treatment. In 1990, Andrews and his colleagues undertook a meta-analytic review of the offender rehabilitation literature and categorized the studies according to their adherence to the RNR model. They found that studies that followed the core RNR principles of risk, need, and responsivity demonstrated the largest reductions in recidivism. In an expanded review of the literature described in the PCC text, this finding was confirmed and further evidence presented on the value of following the other RNR principles (e.g., the organizational principles). For example, services based on the RNR principles and delivered in the community showed a 35-percentage-point reduction in recidivism. Similar services delivered in custodial/residential settings were associated with a 17-percentage-point reduction in recidivism.

PCC's approach to an understanding of crime is to consider the personal, interpersonal, and social supports for criminal action. It is a perspective that is strongly linked to a general psychology of human behavior. GPCSL theory recognizes that criminal behavior is a function of signaled and consequent rewards or costs in interaction with personal biosocial factors (e.g., motivation, cognition, maturation). An important contribution of PCC is the practical products derived from the RNR model. The predictive and crime prevention understanding of criminal conduct has been significantly informed by PCC, and it has played a major role in moving correctional policy away from a punitive approach to a rehabilitative approach.

PSYCHOPATHIC OFFENDERS, TREATMENT OF

Psychopathy is a clinical construct characterized by a set of social, emotional, and behavioral features that, in serious cases, can have destructive social consequences. Socially, prototypical psychopaths often project a smooth but insincere charm, come across as engaging but shallow conversationalists, and are often seen as quite likable by creating a positive yet facile first impression with many people they interact with. However, beneath the surface, they tend to be quite narcissistic, have a grandiose and inflated sense of self-worth, are deceitful and manipulative, and prone to use these qualities to exploit or otherwise take advantage of unsuspecting people they encounter. Psychopaths experience a shallow and limited range of emotion; they form shallow and disingenuous relationships and weak attachments with others. Lacking a conscience and indifferent to the anguish or suffering of others, psychopaths tend to feel little or no regret for wrongdoing. Rather, they are likely to blame victims for their

own misfortunes (e.g., being suckers asking to be taken advantage of), accepting little responsibility for their behavior, and being unconcerned about the rights, feelings, or interests of others. Behaviorally, individuals with psychopathy are impulsive, irresponsible, and lack any sense of commitment to society, people, or causes, making for irresponsible long-term employees, unfaithful spouses, and untrustworthy caregivers. They live in the moment, move about from place to place, and seldom think or worry about the future, often getting bored easily, seeking excitement, and getting tired of routine. They tend to take advantage of the charity and good will of acquaintances or relatives and are prone to committing a range of diverse crimes. Reactive and easily triggered, psychopaths can act out in a violent or assaultive manner if provoked and could just as easily steal a car as they may commit a violent assault, force somebody into unwanted sexual acts, or perform acts of fraud. That said, there is still much debate about the core defining characteristics of psychopathy. This entry focuses broadly on the treatment of psychopathy and reviews key evidence, issues, and concerns in the literature.

Overview

In the popular literature, psychopaths and nonpsychopaths are often depicted as distinct categories. In fact, psychopathy can vary from the mildly psychopathic with only a few features of the disorder to the severe, with many such features. In this entry, the term *psychopaths* is used to describe those with many of the characteristic features and *nonpsychopaths* for those with only a few.

Individuals with psychopathy frequently come in contact with the prison or forensic mental health system owing to their criminal and antisocial behaviors. These behavioral patterns often begin early in life, even during childhood (e.g., with bullying, truancy, theft), and tend to escalate in severity in adolescence and adulthood (e.g., breaking and entering, assault, robbery, and weapon use). Psychopaths can accumulate lengthy criminal careers consisting of a diverse range of crimes. They have high rates of return to prison for new crimes following their release, often for violating the conditions of their probation or parole. Also, there are the so-called white-collar psychopaths who manage to stay one step ahead of the law or operate at the fringes of social acceptability.

With such a collection of unflattering qualities, it may come as little surprise that psychopaths tend not to ask for help or, when help is offered, reject it outright or go along with a take-it-or-leave-it level of enthusiasm.

Psychopathy Checklist-Revised (PCL-R)

A brief overview of the primary measurement device, the PCL-R, is provided because this measure is referenced repeatedly in most discussions of psychopathy. The PCL-R is a 20-item clinical rating scale designed to assess and diagnose psychopathy. Its items were inspired from the work of American psychiatrist Hervey Cleckley, who outlined 16 criteria descriptive of psychopaths but had no formal diagnostic or rating system. Each PCL-R item is rated on a 0 (*absent*), 1 (*characteristic possibly present*), or 2 (*characteristic is present*) rating scale with possible total scores ranging from 0 to 40. Typically scores of 30 or higher are required for a diagnosis of psychopathy. Ratings of the items are based on information gathered from both a clinical interview and from archival sources (e.g., court or prison files, psychiatric records, parole or probation reports). The PCL-R items can be organized into two broad factors: Factor 1 refers to the social and emotional characteristics of the psychopath described previously and can be understood as the personality structure of psychopathy; Factor 2 refers to the chronic antisocial lifestyle pattern, or the behavioral features, of psychopathy. In turn, Factor 1 can be divided into narrower Facets 1 and 2 termed *interpersonal* (i.e., the social characteristics, such as deceitfulness and charm) and *affective* (i.e., the emotional deficit of psychopathy, such as callousness, lack of remorse, and shallow emotions), respectively. Factor 2 can similarly be divided into two facets, 3 and 4, termed *lifestyle* (i.e., the impulsive, irresponsible lifestyle of the psychopath) and *antisocial* (i.e., the diverse criminal behaviors of the psychopath), respectively.

Treatment of Psychopathic Offenders: What the Research Says

Individuals with psychopathy are often resistant to change and challenging to treat. In response to routine prison- or hospital-based treatment programs, psychopaths are often described as

unmotivated, demonstrate little improvement, and have high rates of attrition. Cleckley commented on the absence of psychotherapies demonstrated to be effective for psychopaths in the 1940s. In the decades to follow, similar therapeutic pessimism would be commonplace among authorities in the field, combined with a relative infrequency of treatment evaluations of this group. Many treatment approaches were predicated on trying to change the underlying personality structures rather than reducing antisocial behaviors that are usually the reasons for psychopaths' often prolonged detention in prisons or forensic hospitals.

In 2002, Randall Salekin conducted one of the first systematic reviews of the response of individuals with psychopathy to treatment, reviewing 42 studies that examined programs with clients as being psychopaths or having psychopathic characteristics. Many of the programs are quite dated (some carried out in the 1940s and 1950s) and used outdated treatment approaches. This review identified a broad range of treatments for psychopathic individuals, which included (number of studies in parentheses) psychoanalytic (17), cognitive behavioral (5), therapeutic communities (8), actional procedures (1), eclectic, pharmacotherapy (2), electroconvulsive shock therapy (2), personal construct therapy (1), rational emotive therapy (1), psychodrama (1), or unspecified treatments (1). Eight of the 11 treatments listed had been evaluated by only one or two studies, and with the exception of three treatment types, the authors reported that the patients by and large improved across the programs. The reported success rates by treatments ranged from 59% (for psychoanalytic) to 62% (for cognitive behavioral), to as high as 100% for the single studies. By contrast, electroconvulsive shock therapy (22% success rate), therapeutic communities (25% success rate), and the lone unspecified program (17% success rate) had low improvement rates that were no more effective than control conditions (20% success rate).

Many of the programs in these studies gauged success by positive changes in the attitudes, feelings, and behaviors of their clients such as improved empathy or compassion, increased capacity for guilt, greater anxiety, greater honesty, improvement in social relations, better work or school behavior, improved self-understanding, decreased aggression or impulsivity, decreased hostility, or simply being *less sociopathic*. Not uncommonly, some studies

relied on behavioral changes or reduction in disturbed socialization or other psychological characteristics of psychopathy assessed with paper-and-pencil self-report questionnaires. Few treatments evaluated gains in terms of reductions in new criminal charges or convictions either within the institutional setting or community.

There were a number of methodological concerns in the studies reviewed. For instance, very few of the studies used validated tools, such as the PCL-R, to diagnose psychopathy (partly because it was not developed), with diagnoses frequently based on informal clinical impressions or loose applications of the Cleckley criteria. In many instances, it is uncertain if the programs that were the subject of the studies actually treated psychopaths. Moreover, many of the studies did not examine criminal recidivism as an outcome of treatment, included no follow-up of the patients' posttreatment, had small sample sizes, lacked comparison or control groups, or were based on case studies. Finally, many of the studies featured outdated or antiquated treatment approaches (e.g., electroconvulsive shock therapy), often having predated contemporary principles of *what works* for reducing recidivism. These concerns notwithstanding, Salekin concluded that there was little basis for psychopathy being an untreatable disorder.

Importantly, advances in the theory, practice, and research on the treatment of psychopathy prompted an updated systematic review of this literature by Salekin and colleagues in 2010 based on more contemporary and better designed studies. Salekin and his colleagues noted that, among the new studies published since his initial review, all were either cognitive behavioral in nature or modern therapeutic communities. The newer studies frequently had some form of follow-up and examined criminal recidivism as an outcome and mostly employed the PCL-R to assess psychopathy. In all, the body of research evidence accumulated suggests that treatment can work to reduce the criminal reoffending behaviors of offenders with psychopathy.

Future Directions and Lessons Learned About the Treatment of Psychopathic Offenders

Psychopathy is a serious personality disorder characterized by the remorseless exploitation of others and persistent violation of social norms,

including perpetration of criminal behavior. While psychopaths pose challenges to treatment providers and are difficult to engage and treat, there is no evidence to suggest that psychopathy is untreatable.

A number of lessons have been learned regarding treating psychopathy. First, the definition of the construct matters, and a valid and reliable diagnosis of psychopaths is key. After all, if there is no reliable way of assessing psychopathy, clinicians cannot know whether they are treating psychopaths.

Second, the treatment approach and the organization and delivery of the treatment program matter. The treatability of psychopathic offenders is a thorny topic, and there is little to be gained by evaluating an inappropriate or poorly organized and/or delivered program. The initial Salekin review identified 11 different types of interventions used to treat psychopaths; while some of them generated positive effects and seem to have promise (e.g., cognitive behavioral therapy), others reported clearly less positive outcomes and would seem to be less effective (e.g., therapeutic communities). A crucial task thus involves identifying ingredients of positive or promising programs that may work and taking care to avoid repeating the mistakes of programs that do not work.

Third, the goals and objectives of treatment are critical. The Salekin review noted a bewildering array of possible treatment outcomes and markers of successful intervention: from increased capacity for compassion and remorse, to decreased aggression and improved socialization, to improved performance and attendance in work and school, to reductions in criminal behaviors, and so forth. Some treatment objectives may be more realistic than others (e.g., improving work performance vs. turning a person with psychopathy into a warm and compassionate person) and have more practical benefits for the individual and society. Finally, how programs are evaluated matters. It is difficult to draw conclusions about the effectiveness of a treatment approach for psychopaths if the research design is flawed or weak. Single case studies or small samples, the absence of a comparison or control group, little or no follow-up, or a lack of measurable behavioral indicators of treatment change can greatly weaken the study's design and hamper the conclusions that can be drawn from it.

With these lessons learned, researchers and clinicians should be better informed to understand and work therapeutically with offenders with psychopathy.

PSYCHOPATHIC OFFENDERS: CURRENT STATE OF THE RESEARCH

The Greek philosopher Theophrastus foreshadowed the modern construct of a psychopath, describing such an individual as a *man without moral feeling*, a characterization that has been validated and expanded upon by empirical research. The contemporary understanding of psychopathy, as greatly established by Hervey Cleckley and Robert Hare, is a constellation of pathological traits and behaviors that appear on a continuum in the general population. Clinically diagnosable psychopathy is found in about 1% of the general population and 15–30% of offenders in North American correctional settings. Research

indicates that the traits characterizing psychopathic individuals, including anomalous thought processes, affective processes, language, and behaviors, render them predatory, sometimes dangerous, people. Yet there is no known truly effective *treatment* for this condition. This analysis of one of the most researched pathological personality conditions explores life-span criminal patterns associated with psychopathy through a scientific lens. Furthermore, although the current state of research has allowed psychologists and criminologists to paint a detailed picture of a psychopathic offender, this entry highlights where there is room for further investigation.

Identifying Psychopathy

Psychopathy is associated with a selfish orientation and profound emotional deficit (lack of remorse and empathy), as evidenced from studies of psychophysiology, neurology, and behavior. In lay terms, psychopathy is associated with little or no *conscience*. The psychopath's fearlessness and diminished capacity for morality appear to have biological underpinnings; neuroimaging research indicates reliable structural and functional abnormalities, including gray matter reductions in frontal and temporal areas and anomalies in the prefrontal cortex, corpus callosum, and hippocampus. However, psychopathy is not associated with cognitive deficits. In fact, psychopaths typically are adept conversationalists, emotional chameleons, and skilled at charming, using, and lying to others for material gain, drugs, sex, or power. Psychopathic offenders, for example, are 2½ times more likely than other offenders to be successful in their applications for parole, despite a much higher rate of reoffending. Some use their penchant for conning others to become cult leaders (e.g., David Koresh), powerful politicians (e.g., Joseph Stalin), or corrupt corporate leaders (e.g., Bernard Madoff).

Because of the negative implications of the label *psychopath*, it is not one that should be applied lightly; individuals classified in this manner have scored highly (typically more than 30/40) on Hare's Psychopathy Checklist-Revised, considered the gold standard for measuring the construct. These scores incorporate two key factors characteristic of psychopathy: interpersonal/affective propensities (e.g., grandiosity) and antisocial

or socially deviant behaviors (e.g., proneness to boredom). However, these two factors have been expanded to four *facets* as a result of refined research since the late 1990s: interpersonal (e.g., cunning/manipulative), affective (e.g., callousness), lifestyle (e.g., irresponsible behavior), and antisocial (e.g., criminal diversity) features.

Psychopathy Across the Life Span

Psychopathy is not unique to a particular age or gender demographic. Callous and unemotional (CU) traits, such as lack of remorse and engaging in premeditated aggression that precede adult psychopathy, have been documented in children as young as 3 years of age. CU traits appear to represent one foundation to a lifelong pattern of antisocial and sometimes predatory behavior. For example, juvenile offenders with such features perpetrate more severe violence on their victims and victimize more targets relative to other youth offenders. Youth typically are assessed for psychopathy using the Childhood Psychopathy Scale or the Psychopathy Checklist-Youth Version. Heightened scores on the Psychopathy Checklist-Youth Version have been found to be predictive of psychopathic traits into adulthood and violent recidivism. It has been established that a psychopath is likely to desist in overt, antisocial behavior with older age while the core callousness is unremitting. However, the identification of optimal diagnostic tools and how well such measures predict problematic future behavior is an ongoing research focus.

Psychopathic Offenders

Clinically diagnosable psychopaths are overrepresented in North American prisons. Both juvenile and adult psychopathic offenders commit more crimes, more severe crimes, and are more likely to reoffend relative to other offenders. The unusual motivations for violent and nonviolent crimes that set psychopathic offenders apart from their counterparts are boredom, a need for stimulation, and thrill-seeking.

Violent Offenders

A psychopathic individual often shows a pattern of high sensation-seeking drive and low self-control,

such that violence and predation in general can be an exhilarating adrenaline rush. Furthermore, psychopaths lack *brakes*, so to speak; their lack of concern for the welfare of others, fearlessness, and impaired ability to identify fear responses in others leave no mechanism to inhibit their urges. A psychopath will act aggressively if it will achieve short-term internal or external goals.

Research indicates that psychopathic offenders readily engage in both reactive and instrumental violence. Also known as *cold-blooded violence*, instrumental violent crimes are associated with premeditation and a clear external goal. This type of violence is more rare among violent offenders than *reactive* aggression, which is impulsive and results from provocation by threat or antagonism. In a 2007 analysis of homicides committed by both psychopathic and nonpsychopathic individuals, 88.9% of homicides committed by psychopaths were instrumental in nature, more than double that of their nonpsychopathic counterparts. However, such individuals are able to convincingly justify their crimes as having been reactive in nature, to the extent that they often receive convictions for lesser categories of homicide (such as manslaughter) and are treated more leniently throughout the criminal justice system.

Research has demonstrated that the psychopath's affinity for violence of a predatory nature persists across time and a variety of violent offenses. For example, children with CU traits use more premeditated aggression against their peers. Adult psychopaths are disproportionately more likely to commit instrumental domestic homicides (e.g., for insurance money) in an emotionally detached fashion. Among adult offenders, criminals with psychopathic traits not only offend quicker upon release but also commit more serious violations of conditional release.

The Sexual Psychopath

Throughout the 1970s, Ted Bundy perpetrated the violent, sadistic murders of numerous women and girls of varied ages. In Canada, Paul Bernardo and wife Karla Homolka abducted, raped, and murdered teenage girls, documenting the crimes on camera. While these offenders are notorious psychopaths, their crimes suggest a specific focus of

thrill-seeking that is sexual in nature and has been designated as *sexual psychopathy*. Sexual psychopaths are defined by extreme thrill-seeking motivations in combination with sexually deviant activities. They are not necessarily sexually deviant in terms of a paraphilia but rather focus their sensation-seeking by sexually victimizing others. Such offenders are dissimilar to other psychopathic offenders and sex offenders in terms of victim selection, violent behavior, and patterns of recidivism.

In great part due to a pervasive need for stimulation when prone to boredom, sexual psychopaths do not usually fixate on an exclusive victim type (e.g., adults or children) but rather vary their victims' demographics. While the majority of psychopaths who commit sexual assaults appear to prefer adult victims, as many as 16.8% offend against both children and adults. These individuals are known as *mixed offenders*, a group with one of the highest base rates (about two thirds) of psychopathy ever identified in a criminal typology. Furthermore, higher psychopathy scores are indicative of more severe and varied violence in sexual offenses for both adult and adolescent offenders. For example, one such offender was documented explaining that his repetitive cycles of sexual attacks on children followed by adult female victims occurred because *I just got bored*.

In addition to this sexual thrill-seeking motivation, sexual sadism, or a pattern of sexual arousal derived from sexual violence, is found to be elevated in psychopathic offenders; as a general rule, such offenders tend to incorporate unnecessary and sadistic violence in their attacks, including sexual homicides. In fact, psychopathic traits are found in the vast majority of sexual homicide perpetrators, and as many as 82% of psychopaths have been found to engage in sadistic violence (torture, overkill) during these crimes.

Psychopathy is associated with a higher rate of recidivism for sexual violence. A combination of high psychopathy scores and sexual deviance seems to be particularly dangerous, greatly increasing the likelihood and speed of recidivism. Among sexual offenders specifically, those high in psychopathy fail faster upon release compared to those low in psychopathy. Furthermore, mixed offenders tend to reoffend faster than other sexual offenders; they are 2–10 times more likely to do so.

Treatment of Psychopathy

The current state of research regarding the treatment of psychopathy remains contentious. Given the early presentation of psychopathic and CU traits, researchers hope to prevent deviant behavior through the treatment of children and youth. As such, the foremost research question is: Can successful treatments be applied when early red flags are identified? One sample of juvenile offenders high in psychopathic traits exposed to intensive treatment took longer to commit a new offense and showed a significant reduction in the likelihood of violent reoffending. However, such outcomes are not consistent. Few individuals have shown a reduction of such traits through intervention at an early age. Rather, psychopathic traits have been shown to remain relatively stable into adulthood despite treatment. This raises the question of whether youth should be designated as psychopathic via clinical testing; diagnoses may produce stigma-associated problems but may also lead to timely treatment when the individual may be most impressionable.

It appears that a common barrier to successful treatment is poor compliance and motivation. However, research also has found that psychopathic offenders who engage in therapy have a greater chance of violently reoffending compared to nonpsychopathic participants. It is likely that psychopaths apply the tools acquired in therapy, such as social skills and an understanding of others' emotions, to gain skill in exploiting new victims. For example, sexual offenders high in psychopathic traits who actively partake in therapy (e.g., completed homework) are significantly more likely to reoffend with a serious crime. Given that psychopathy not only prevails across the life span but also is associated with violent nonsexual and sexual crimes, identifying the optimal path of treatment has and will continue to be a priority of research endeavors.

Future of Scientific Research

Given the powerful implications of psychopathy in decision-making throughout the criminal justice system, improving the scientific understanding of

this condition should be a priority. As of 2018, the state of research for psychopathic offenders is promising. Thanks to the legacy of Robert Hare and an ongoing international effort focusing on psychopathy (including the scholars comprising the Society for the Scientific Study of Psychopathy), the understanding of criminal psychopathy in terms of life-span development, language, physiology, neuroscience, emotional (including fear) deficits, predatory behavior, and patterns of recidivism has advanced significantly. The construct of sexual psychopathy and a primary thrill-seeking motivation is increasingly supported in research. However, the basis of this thrill-seeking motivation is still poorly understood. Why do children with CU traits enjoy being mean to others? Why are psychopathic offenders so driven by sensation-seeking?

As mentioned, research aimed at developing optimal treatment strategies to use with psychopathic offenders will continue. However, since the turn of the 21st century, research questions have become increasingly focused on *everyday* or *successful* psychopathy—seemingly likable individuals who may prey on others in nonviolent but destructive ways. Some researchers suggest that there is a growing population of psychopaths in the corporate sector who are highly motivated by financial gain and cunning enough to become masterminds of white-collar crime. This persona is in sharp contrast to the type of psychopathy on which most current research is based—incarcerated and sometimes violent criminals. As a result of this latest revelation, future research should strive to understand how psychopaths select and manipulate their victims. Avenues of research should include assessing the Internet and the workplace as hunting grounds for predatory psychopaths. Results may clarify what potential victims can do to avoid being pulled in by the charming psychopath. As such, it stands to be that identifying the *everyday* psychopath and understanding how to protect his or her *everyday* potential victims is the research of the future.

PSYCHOPATHIC OFFENDERS: INEFFECTIVE TREATMENT PROGRAMS

Although treatment methods are intended to be helpful, sometimes even with the best of intentions, certain treatment methods can fail. This highlights the need to evaluate treatment practices to help establish what does and does not work for rehabilitating offenders and decreasing their criminal behavior. Research reviews have identified what are likely unsuitable programs, such as electroconvulsive shock therapy or some therapeutic community programs, which generated weaker treatment effects or even had iatrogenic effects (i.e., they made clients worse). Certain ineffective and inappropriate programs such as these only contributed to the prevailing belief that *nothing works* with this population. As such, this entry discusses treatment methods attempted with psychopathic offenders, which were demonstrated through research to be ineffective, offers possible explanations as to why these approaches did not work, and discusses positive steps forward for more effective approaches.

Ineffective Programs: A Case Illustration of the Penetanguishene Mental Health Centre Therapeutic Community

A classic psychopathy treatment outcome study was conducted out of the Penetanguishene Mental Health Centre in Ontario, Canada, in the late 1980s. The institution was a maximum security psychiatric facility that housed mentally ill offenders, many of whom had often committed violent crimes and were found not criminally responsible on account of mental disorder. Others were held temporarily on remand, awaiting trial or sentencing. The evaluation featured a program developed in the 1960s by Canadian psychiatrists Elliot Barker and Barry Boyd, who sought to create an environment or milieu within the institution that would be conducive to self-understanding and behavioral change. The program was a variant of the therapeutic community approach to treatment first developed by Maxwell Jones at the Henderson Hospital in England but differed in several important respects.

The treatment was intensive and involuntary, with the men placed in a group in close quarters, at times handcuffed together or locked in a room with padding on the lower walls, often for hours on end. There, the men were left to engage in discussion and to confront and challenge each other on their behaviors. Because the treatment program often was peer operated, the men had little contact with professional staff and were essentially tasked with running their own treatment. Group pressures were combined with sleep deprivation, fasting, and often the use of hallucinogenic substances or sedatives (e.g., scopolamine, sodium amytal) to lessen defenses and reduce inhibitions. Patients could even make recommendations for others to receive injections to achieve therapeutic gains. Patient testimonials after the group attested to the psychological toll of the therapy. Not uncommonly, lower risk men were placed in a group with high-risk, mentally ill men who had committed serious violent offenses, and assaults on copatients occurred. Patients would also often labor under the effects of the injections, sometimes experiencing terrifying hallucinations that were far from therapeutic.

The evaluation of this program compared 176 men who had participated in this therapeutic community to a sample of 146 men who did not. The men were also rated on the Hare Psychopathy Checklist–Revised on the basis of their institutional file information. This permitted the creation of four comparison groups on the basis of treatment status and psychopathy diagnosis: psychopathic offenders who did or did not attend the therapeutic community and nonpsychopathic offenders who either attended or did not attend the therapeutic community. The men were matched on age, criminal history, and index offense as a means of controlling for baseline risk given that such characteristics can impact the outcome variable. The men were followed up for more than 10 years postrelease, and rates of violent reconviction were compared among the four treatment and no treatment groups. Among the nonpsychopathic men, those who attended the therapeutic community had lower rates of violent recidivism in the community (22%) than those who did not (39%). Among the psychopaths, however, the men who attended the program demonstrated significantly higher rates of violent recidivism (77%) than psychopathic individuals who did not (55%). With an approximate one-third increase in observed rates of posttreatment violence in the community, the therapeutic community appeared to make psychopathic individuals worse. The researchers concluded that this program was clearly the wrong type of therapeutic community for psychopathic offenders.

An unfortunate consequence of this evaluation was that it was widely influential in a number of unanticipated ways, with several scholars and service providers generalizing the finding to all treatment programs and even concluding that psychopaths were either untreatable or that treatment should not be provided for them. The Penetanguishene psychopathy therapeutic community study was a thorough evaluation of a clearly inappropriate program that appeared to be iatrogenic for high-risk men. Although it was an excellent illustration about what not to do therapeutically with psychopathic men, it was hardly illustrative of all programs. It would be inappropriate to generalize its findings to programs that operated according to different methods and had different treatment foci.

Characteristics of Ineffective Programs

So what exactly made this program ineffective? What does it have in common with other programs that may have had iatrogenic effects or simply null results? Are most therapeutic communities operated in this manner? Aside from some of the more obvious harmful elements (e.g., forced administration of powerful psychoactive substances), there are a number of important qualities that characterize ineffective programs such as this.

Overtreating Offenders

One significant concern was that the men were simply overtreated. Humans have limits in their ability to encode, retain, and process information, and after a period of time will reach their saturation point. Offenders are no different, and the ordinary frailties of human information processing ability and retention are ever present, if not more pronounced, in this population. Experts suggest that high-intensity programs should not exceed 10–15 hours of focused treatment intervention per week; moderate- and low-intensity programs involve considerably lower dosages. Beyond this, it becomes extremely challenging for people to retain, and to be able to effectively use, any skills or strategies delivered in treatment. By contrast, the Penetanguishene therapeutic community involved around 80 hours of therapy per week. This far exceeds the threshold of benefit that an individual is likely to receive from any treatment.

Mixing Low- and High-Risk Offenders

The men were indiscriminately routed into the treatment program with little consideration for their risk level or degree of dangerousness, the severity of their presenting concerns, the dosage of treatment they may require, or the potential dynamics that may result from integrating low- and high-risk offenders. As it turns out, the low-risk men, and those who were nonpsychopathic specifically, did not demonstrate higher rates of recidivism but could have been vulnerable to being victimized by higher risk, psychopathic, and sometimes dangerous men, in addition to being exposed to antisocial role modeling and attitudes.

Failure to Target Criminogenic Need

These programs were loosely structured and did not target essential dynamic or changeable risk factors demonstrated to predict recidivism (e.g., criminal attitudes, negative peers, employment and education deficits) and which may have causal relevance to criminal behavior. Granted, in the 1960s, the program's developers did not enjoy the benefits of these relevant research findings. The program instead focused on breaking down defenses and developing personal insights using what is now considered unethical and draconian means. The men, at best, would walk away perhaps learning more about themselves and others but would still have many of the skill deficits and attitude problems that contributed to their criminal and antisocial behaviors initially.

Inappropriate Therapeutic Foci

Early programs often had inappropriate treatment emphases. A common treatment focus was the character structure of the psychopath, that is, attempting to help individuals develop greater empathy and compassion, experience emotional states, display sensitivity to the interests and feelings of others, and to develop the capacity for remorse or guilt. Playing on the conscience of psychopaths was not particularly effective given the stability of these personality traits. Research also shows that there may be a neurobiological component to callous and unemotional features, which would also naturally point to a high level of stability. In addition, attempts to engender greater compassion and emotional sensitivity in psychopathic offenders led to the possibility that any skills gained in treatment could be misused, for instance, to become more effective at manipulating and exploiting others.

Unresponsive Interventions

The interventions used in this program were clearly ineffective, and, in many instances, they could have a deleterious impact. There is no evidence that group pressure; use of sedatives, hypnotics, or hallucinogens; and deprivation of food, sleep, or water (essentially drugs or more intensive punishments) bring about constructive or positive

change. When delivered to a group of individuals with fragile mental health or histories of violence, such high-handed pressure techniques could simply backfire (as they did). Many of the interventions involved unguided, free-flowing discussion, without any formal and structured delivery of skills to target antisocial modes of thinking, aggressive behavior, or difficulties with emotional control. Staff also had little contact with patients or supervision of them, and thus there was limited opportunity for staff to role model prosocial behavior skills or to monitor and reinforce positive behavioral changes in the patients.

A Way Forward

The Penetanguishene therapeutic community served an important lesson for researchers and clinicians about how not to treat psychopaths. To avoid repeating previous mistakes, it is essential to beware of the characteristics of ineffective programs. At best, such programs simply have no impact and clients do not improve; however, more troubling is that such programs can be iatrogenic and run the risk of making clients worse. In turn, knowing what does not work can help inform a way forward toward identifying what might work.

A common thread among inappropriate programs is that they failed to respond to the principles of effective correctional intervention. These principles are the

- (1) risk principle, that is, matching program dosage to client risk level;
- (2) need principle, that is, prioritizing criminogenic needs linked to recidivism in treatment; and
- (3) responsivity principle, that is, adjusting treatment services to the unique characteristics and challenges of clientele, such as motivation, culture, learning style, or personality, all to promote engagement and retention.

Adherence to the Risk-Need-Responsivity principles translates into a respect for client dignity and provides the conditions conducive to changing destructive behavior patterns. Many ineffective programs also predated the development of Risk, Need, and Responsivity. Lacking the

knowledge about what works in correctional treatment led to many failed attempts before more effective programs would be established.

PSYCHOPATHIC OFFENDERS: PROMISING TREATMENT PROGRAMS

Psychopathy refers to a serious personality disorder characterized by a host of problematic interpersonal, emotional, and behavior features. Interpersonally, psychopaths are charming, deceitful and manipulative, and inflated in their self-appraisals. Emotionally, psychopaths are devoid of the normal emotional range of human experience; they lack a sense of guilt or remorse for wrongdoing, have a callous disregard for the feelings of others, and externalize the blame for negative behavior. Finally, behaviorally, psychopathy has destructive social consequences, as psychopaths lead an impulsive, irresponsible, chronically antisocial lifestyle that is frequently fraught with a miscellany of reckless norm and rule defying behavior that often brings them in conflict with

the justice system. This entry describes a contemporary model of psychopathy treatment, followed by an illustration of its implementation and a review of the empirical research of treatment outcome studies. A number of other promising treatment programs are also outlined.

A Two-Component Model for the Treatment of Psychopathic Offenders

Developed by Stephen Wong, this treatment model for offenders with psychopathy was based on the integration of the research on psychopathy assessment, treatment of personality disorder, and offender rehabilitation. The model's overarching treatment goal is to reduce violent or other criminal behaviors of the individual with psychopathy.

Component 1, or the interpersonal component, is associated with the interpersonal and affective personality features of psychopathy captured by Factor 1 (F1) of the Psychopathy Checklist–Revised. These features include presentations of being glib and superficially charming, egocentric, manipulative, callous, lacking in remorse or guilt, and lack of empathy—in other words, generally what a layperson often considers characteristics of psychopathy. Component 2, or the criminogenic component, is associated with features of antisociality and dysfunction lifestyle captured by Factor 2 (F2) of the Psychopathy Checklist–Revised. Features such as impulsivity, irresponsibility, lacking in realistic life goals, emotional and behavioral problems, and criminality are some of the defining features. These criminogenic features are essentially the risk and need domains of the Risk-Need-Responsivity principles, and treatment to reduce reoffending must be directed at these features. F1 characterizes the psychopathy personality, but F1 is not predictive of violence and reoffending; F2 features consistently and strongly predictive reoffending. Though counterintuitive, treatment of the psychopathic personality disorder to reduce violence and criminality needs to focus on changing F2 antisocial and offending problems rather than changing the core F1 psychopathic personality features.

The F1 personality features have been shown to be stable across the life span, while the F2 criminality features decrease with age and, therefore,

are potentially changeable. Changing F1 would be tantamount to attempting to change those with psychopathy into warm, empathic, honest, and caring beings. Not only are such attempts difficult and likely to fail, but F1 personality features are also not very relevant to predicting risk. While individuals with such features often behave in ways that are unpleasant and vile, such behavior is not illegal. Although Component 1 is not of central relevance to risk reduction treatment, individuals with F1 characteristics are challenging to work with in treatment programs: They tend to lie, manipulate, not accept responsibility for their actions, and be uncooperative; it is difficult for them to form working relationships (i.e., therapeutic alliances or bonds) with staff. Staff require special clinical skills to work with such individuals to retain them in treatment, to reduce treatment attrition, and to maintain treatment integrity, that is, to ensure that treatment is provided as designed. Staff needs to manage the interpersonal and emotional features of psychopathy as a responsivity issue.

Implementing Component 1

Implementing Component 1 involves the following:

- Managing treatment-interfering behaviors—Staff needs to expect, understand, and carefully manage these treatment-challenging behaviors that are a part of the pathology and are reasons for treating those with psychopathy rather than reasons for discharging them from treatment. Exercising a great deal of patience, understanding, and compassion, while being firm but fair, is required when working with these clients in order to maintain program integrity and to ensure the progress of other patients is not jeopardized.
- Working as a cohesive team with open lines of communication—Teamwork with mutual support, shared goals, and clear and open communication with one another and with the individual with psychopathy are necessary to ensure all are working together in treatment delivery. Problems need to be resolved promptly, and staff members should support each other through challenges to keep morale high.
- Using motivational interventions—Most individuals with psychopathy are likely resistant to change. A clinical strategy termed *motivational interviewing* can be very helpful. In short, this involves (a) expressing empathy (i.e., providing validation of the client's struggles), (b) developing discrepancy (i.e., showing how their behaviors get in the way of achieving their goals), (c) rolling with resistance (i.e., creatively using their resistance as momentum for change), (d) supporting self-efficacy (i.e., reward and support clients' positive changes to build confidence in their ability to change), and (e) avoiding argumentation (i.e., avoiding unhelpful power struggles).
- Maintaining clear boundaries—Respect and maintain professional boundaries in terms of information sharing and respectful interaction with one another and with clients. Model the very behaviors, such as good boundaries, staff wish clients to display. Offenders testing limits and pushing boundaries are to be expected, while staff need to develop strategies to deflect and manage boundary intrusions.
- Managing one's own reactions—Staff need to be aware of their own positive or negative emotional reactions while working with clients with psychopathy. They need to manage these reactions so that they can continue to interact with clients in a professional, helpful, and effective manner so as to assist them in their journey to make changes to their behaviors.
- Adapting the working alliance—The client's F1 interpersonal and affective personality feature can seriously impede the forming of emotional connection or therapeutic alliance between therapist and client. Instead, therapists can focus on setting shared tasks and goals of treatment that will help clients learn new skills to reduce their recidivism risk.

Implementing Component 2

Considerations in implementing Component 2 include the following:

- Targeting criminogenic needs—Treatment should target risk factors linked to violent and antisocial behaviors or criminogenic needs that have led to and maintain criminal behavior.

The Central Eight model of criminal behavior identifies criminal history, procriminal attitudes, criminal peers, antisocial personality pattern, employment/education concerns, family/marital concerns, drug and alcohol problems, and poor use of leisure time. For other client groups such as sexual offenders, reducing sexual deviance (e.g., atypical or illegal sexual interests, compulsive sexual behavior) is often necessary, while violence-prone offenders may need to improve anger control. Risk assessment tools with dynamic, or changeable, risk factors such as the Level of Service/Case Management Inventory or the Violence Risk Scale can be used to identify criminogenic needs.

- Using cognitive behavioral approaches—The primary treatment approach for Component 2 is cognitive behavioral treatment (CBT), that is, offenders learn to change their ways of thinking leading to or in conjunction with positive changes in their behaviors. With CBT, offenders also learn skills and strategies to change feelings (e.g., anger) and behaviors linked to criminal behavior.
- Helping clients develop prosocial behavior skills—Treatment involves teaching offenders a new repertoire of skills and strategies (i.e., new ways of thinking, feeling, and behaving) or strengthening existing positive skills to replace offense-related modes of functioning. This involves recognizing examples of less serious but still negative behaviors to avoid punishment, for example, using verbal instead of physical aggression to intimidate others. Such negative behaviors (what have been called *offense analogue behaviors*) signal some criminogenic needs that are active, and the individual needs to develop new prosocial behaviors (what have been called *offense replacement behaviors*) to replace the negative behaviors.

For instance, under stress, an individual may have reacted aggressively (e.g., swearing, breaking objects, or even physically assaulting someone). Replacing negative with positive thinking (e.g., “being aggressive won’t make the situation any better”), substituting counterproductive feelings with constructive skills (e.g., distraction or deep breathing to reduce bodily arousal associated with

anger), and replacing aggressive with assertive behaviors (e.g., assertively and respectfully standing up for one’s rights) are the treatment goals to resolve problems (e.g., walk away to cool off before addressing the issue). The goal is to reinforce and encourage offense replacement behaviors, while reducing the frequency of offense analogue behaviors.

Treatment Outcome Research of Promising Programs

An updated systematic review of treatment outcome studies of offenders with psychopathy completed by Randall Salekin and colleagues showed overall better quality studies, treatment programs, and outcome evaluation approaches that paralleled many advancements made in the field. Most programs identified in the review use CBT or similar therapeutic approaches. Therapeutic communities when used are more structured and supplemented by other useful adjunctive interventions. Outcome evaluation usually includes a period of follow-up, with a control or comparison group using reduction in postprogram recidivism or other objective markers of success. Psychopathy and risk, almost without exception, were assessed by validated tools such as the Psychopathy Checklist–Revised.

More specifically, two high-intensity sex offender treatment programs in mental health facilities operated by correctional services in Canada have generated promising results based on CBT treatment approaches. The Clearwater Program, based in the province of Saskatchewan, found that decreases in risk of violence or sexual violence, measured between pretreatment and posttreatment on a clinical rating scale, were significantly associated with decreased sexual and violent recidivism in the community. That is, the more treatment change men made in resolving problems identified by dynamic risk factors, the less likely they were to be convicted for new violent offenses or sex offenses after their release, even after accounting for psychopathy. The second program based at the Regional Treatment Centre in Ontario also found that individuals with psychopathy who were assessed as having reduced their risk at the end of treatment had lower rates of violent recidivism than those assessed as not having lowered their risk. Moreover, in a large sample

of sex offenders treated at the Warkworth Sexual Behavior Clinic in Ontario, it was found that offenders with psychopathy showing positive behavior in treatment had significantly lower rates of sexual reoffending than their counterparts with negative behavior in treatment.

A group of male nonsexual offenders who were high risk and high psychopathy were treated at the Aggressive Behavior Control Program, also located in the same mental health facility as the Clearwater Program in Saskatchewan; they showed risk reduction associated with reduced violent recidivism after release to the community. In a separate study, a similar smaller group of treated clients with high risk and high psychopathy was compared to matched untreated controls in their recidivism in the community. The treated group showed significant reduction in the severity of recidivism.

In a number of treatment facilities in the Netherlands, schema therapy was used to treat patients with personality disorder, some with significant psychopathic features. Schema therapy therapists focus on remediating the patient's early unmet developmental needs to foster a secure attachment as well as more adaptive coping and emotional states. Short-term outcomes showed promise, but no long-term recidivism reduction outcomes have been reported.

The Chromis program, developed for offenders with psychopathy in early 2000 by the National Offender Management Service in the United Kingdom, also uses schema therapy-based approaches, together with teaching problem-solving and conflict resolution skills, to reduce problem and criminal behaviors. Staff are carefully selected and trained to work with this offender group. Short-term outcomes with relatively small sample sizes are encouraging, but no long-term recidivism outcome evaluation has been reported.

In 1998, the New Zealand Department of Corrections developed a treatment program for high-risk offenders, many of whom have significant psychopathic features. Treatment is guided by the Risk-Need-Responsivity model and uses CBT and social learning approaches to help offenders change their problem behaviors. The program accommodates the special needs of the indigenous (Māori) participants although the program is not based on an indigenous model. Short- and

long-term treatment outcome evaluations showed statistically significant reductions in reconviction for violence and breach of parole conditions.

Final Thoughts

What has been described in this entry is a treatment model for psychopathy developed based on contemporary research on psychopathy, treatment of personality disorder, and offender rehabilitation together with key considerations on how to implement the model. The research evidence suggests that the Risk-Need-Responsivity principles of offender assessment and treatment can be generalized and applied to offenders with psychopathy. In providing treatment to them, it is paramount that clinicians provide close observation and carefully manage treatment-interfering behaviors. The other challenge is to deliver evidence-based treatment interventions so that they target criminogenic needs to reduce antisocial or negative behaviors, while encouraging the development of prosocial skills and strategies to meet the offenders' needs in positive ways. Although the evaluation of promising treatment programs is in its early stages, the research suggests that cautious optimism is warranted.

PSYCHOPATHIC OFFENDERS: TREATMENT CHALLENGES AND CONTROVERSIES

The very nature of the interpersonal, emotional, and behavioral features that characterize psychopathy, and its destructive social consequences, would seem to lower optimism about the response of psychopaths to treatment. The process of treatment is challenging, requiring honest self-reflection, receptiveness to often critical feedback, and the motivation to make important behavioral changes to prevent the same problems in life from resurfacing. The therapeutic pessimism associated with treating offenders with psychopathy is naturally due in large part to the many challenges they present in therapy and their resistance to therapeutic efforts to bring about change. This entry reviews the treatment challenges and controversies of treating offenders with psychopathy; although the challenges are many, the task is not insurmountable, especially when psychopathy is given a realistic context.

Putting Psychopathy Into Context

One important source of context is the media. The media has extremely negative portrayals of individuals who commit serious crimes, such as sexual assault and murder, and understandably so. Many such individuals (e.g., Ted Bundy, Jeffrey Dahmer, and Charles Manson) probably were psychopaths. In the cinema, villainous characters who commit ghastly crimes and inflict murder and mayhem in films such as *Silence of the Lambs* and *Cape Fear* are depictions of probable

psychopathic characters. But one wonders if such individuals are common in the real world if they are typical of all psychopaths.

Research demonstrates that although psychopaths are more likely to be found in prison settings, they tend to be among a minority, accounting for at most 15–25% of incarcerated men in custody. Psychopathy occurs along a continuum in which individuals, including offenders, vary from possessing few or no psychopathic characteristics to having many such features. Even among men who commit serious crimes, most of them are not actually psychopaths. Some high-intensity violence reduction programs will have base rates of psychopathy as high as 50% among their treatment attendees, while for sex offenders, approximately one third of rapists will have some psychopathic features, and typically, a much smaller proportion for men who molest children (generally around 5–10%) will be psychopathic. Most men in offender treatment programs, however, will not be psychopathic; thus, psychopaths attending treatment will be routinely interacting and engaging with nonpsychopaths.

Media portrayals, both fact and fiction, present psychopaths as violent, sadistic, high-risk individuals who are destined to reoffend. It must be asked whether this reflects reality. Research from meta-analyses has demonstrated that high scores on the Hare Psychopathy Checklist–Revised (PCL-R), or a diagnosis of psychopathy more specifically, are good predictors of violent reoffending and any reoffending in general, although the PCL-R tends to be a somewhat weaker predictor of sexual reoffending. What this means, interestingly, is that not all psychopaths reoffend sexually, violently, or even in general. Routinely, approximately one quarter of men with psychopathy are not convicted of a new serious offense, what some have termed the *nonrecidivating psychopath*. What these findings reveal further is that not all men with psychopathy are at high risk of violence or sexual violence, and there will be a nontrivial number who do not go on to commit new serious offenses. However, these empirical findings are often overlooked or not considered, and the specter remains about the psychopath's notorious unresponsiveness to intervention.

Therapeutic Challenges With Offenders With Psychopathy

It is generally accepted that psychopaths are hard to treat, and they pose a significant challenge for service providers to engage clinically. What follows are a number of the therapeutic obstacles that could prevent psychopaths from making fuller gains in treatment.

Experience Higher Rates of Dropout

A large-scale meta-analysis of predictors of offender treatment attrition found high scores on the PCL-R, or diagnosis of psychopathy based on the PCL-R, to be one of the strongest predictors of treatment dropout. On average, men with psychopathy had a 30% higher rate of dropout from offender treatment programs than men without psychopathy. Scrutiny of the individual studies behind these findings revealed some interesting trends. First, although men with psychopathy had higher rates of noncompletion, most men would successfully complete the treatment programs they were enrolled in. Treatment research conducted on a Canadian high-intensity sex offender program operated through the Correctional Service of Canada found that more than three quarters of men with high PCL-R scores actually successfully completed the program. One of the strongest predictors of noncompletion was high PCL-R Factor 1 scores, and more specifically, the callous and unemotional features (i.e., the Affective facet) of psychopathy. Men who were simply high risk but who did not possess an abundance of these psychopathic emotional features were not at any further risk of dropping out of the program.

Derive Less Therapeutic Benefit

The available research on the topic has demonstrated that offenders with psychopathy tend to derive less benefit from therapy. Research from Correctional Service of Canada violent offender and sex offender programs has also found that PCL-R scores are inversely related to positive treatment changes made in these programs; that is, as levels of psychopathy increase, the amount of change made decreases. While Factor 1 and 2 scores were both associated with decreased therapeutic progress, as with dropout research cited

previously, it was the Affective facet (i.e., the callous–unemotional features of psychopathy) that had the strongest association. In fact, after accounting for the callous–unemotional traits, the other facets of the PCL-R were not significantly associated with decreased treatment progress.

Pose a Challenge to Treatment Engagement

Psychopaths are also challenging to engage therapeutically. Additional research from the same Canadian high-intensity sex offender program referenced previously has found that men with psychopathy tend to have weaker therapeutic working alliances with their treatment providers than men without psychopathy. Some aspects of the working alliance also appear to be affected differently by the characteristics of psychopathy. For instance, scores on the Working Alliance Inventory therapeutic bond scale, which measures the emotional connection between client and therapist, were negatively associated with PCL-R Affective facet scores; that is, a high level of callous–unemotional features was associated with weaker therapeutic bonds. This makes sense, given that a shallow emotional style and lack of empathy would seem to preclude the ability to form a caring and emotional connection with the therapist. This difficulty in forming an emotional therapeutic bond could serve as a source of frustration and discouragement for therapists, who naturally may wish to connect affectively with their clients and who view the quality of their relationship as a marker of treatment progress.

Exhibit Low Treatment Motivation and Poor Therapeutic Work Ethic

In addition, the Lifestyle facet of the PCL-R (i.e., a pattern of impulsive and reckless behaviors) had particularly strong associations with the task scale of the Working Alliance Inventory, which measures the engagement of therapeutically relevant tasks in a session (e.g., working on changing criminal attitudes). Given that the characteristics of the Lifestyle facet include irresponsibility, lack of goals, impulsivity, and parasitic qualities, it is possible that the association with task scores reflected low motivation and poor therapeutic work ethic. For instance, psychopaths who score

high on the Lifestyle facet may have less willingness to complete homework assignments or engage in meaningful therapeutic interventions.

Often Disruptive in Treatment

Research and clinical experience on this topic demonstrate that psychopaths are often disruptive in treatment: They may crack jokes, heckle, interrupt, or argue with the group facilitator or may incite conflict with group members. This can have the effect of derailing the session. Some psychopaths can also have abrasive interpersonal styles, which can cause conflict with staff and other treatment participants, sometimes even creating safety concerns for themselves or increasing their risk of being expelled from the treatment program; hence, the increase in dropout rate.

Display Manipulative and Deceitful Behavior

Psychopaths can display manipulative behavior in treatment, trying to con or request special favors or privileges, in some cases colluding with staff in illegal acts such as bringing in contraband. Perhaps most destructive, a clever psychopath can engage in staff splitting in which they pit one staff or a group of staff against another. For example, one staff may serve as a mouthpiece or advocate for the offender, while another staff may see through the offender's manipulative tactics and could get into a row with the other staff member. Some psychopaths can tear apart an entire treatment team that becomes embroiled in conflict and disagreement over a single patient.

Exhibit Inappropriate Behavior and Strain Boundaries

Psychopaths, with their superficial charm and charisma, can be flirtatious, engage in sexualized or inappropriate comments or gestures toward staff or patients, and in some instances, even become involved in sexual intimacies with staff or patients. They may pry personal details out of staff members about their lives and then use this information for blackmail or to try to develop a personal and nontherapeutic relationship with the staff member.

Use Abusive and Intimidating Interactions to Control Others

Psychopaths can be hostile, belligerent, and verbally and emotionally abusive in their interactions. This is often a long-held strategy that has yielded payoffs for them in the past, as people kowtow to their demands or walk on eggshells around them out of fear of provoking them. This can happen with staff and patients. As a result, psychopaths are not held accountable for their behavior, and they are given little incentive to change. These and other behaviors from the psychopath can trigger countertransference reactions (i.e., the therapist's feelings and reactions toward the patient) in staff members, where they may retaliate and become angry and abusive toward the patient, respond in a fearful and submissive manner, or develop romantic or sexualized feelings—all of which run counter to the purposes of treatment and can have dire consequences for staff member and patient.

Final Thoughts

With the many therapeutic pitfalls and challenges that come with working clinically with offenders with psychopathy, one may wonder what a therapist can do to overcome these challenges. Critical to responding to such challenges is for staff to manage the treatment-interfering behaviors of psychopaths, so that they can be retained in treatment in order to realize the maximum benefits from the treatment. What this review demonstrates is that there is the potential for a lot to go wrong very quickly if staff are not appropriately trained, do not carefully monitor treatment-interfering behaviors, and do not openly communicate their observations among all treatment team members to prevent minor problems from escalating. Armed with appropriate knowledge, skills, and strategies to manage the treatment challenges that individuals with psychopathy bring, many potential problems can be averted to the benefit to the staff, the patient, and the program.

PSYCHOPATHIC PERSONALITY INVENTORY–REVISED

The Psychopathic Personality Inventory–Revised (PPI-R) is the revised version of the Psychopathic Personality Inventory (PPI), a widely used self-report measure of psychopathic personality (psychopathy). The PPI-R, like its predecessor, is designed to detect the core personality traits of psychopathy, including superficial charm, fearlessness, guiltlessness, manipulativeness, dishonesty, grandiosity, callousness, externalization of blame, and poor impulse control. It excludes items explicitly assessing overt antisocial and criminal behaviors to permit investigators and clinicians to focus on psychopathic personality traits per se. As a consequence, compared with many other psychopathy indices, the PPI-R may better distinguish psychopathy from the conceptually and empirically overlapping construct of antisocial personality disorder (ASPD) in the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition*. ASPD, in contrast to the largely personality-based condition of psychopathy, is operationalized in terms of

a long-standing antisocial and criminal behavior and is virtually by definition maladaptive.

Prior to the development of the PPI, most research on psychopathy was limited to offenders, largely because most extant measures of this condition required access to detailed corroborative (e.g., file) information. Perhaps partly as a consequence of the field's focus on criminal samples, most psychopathy measures were largely maladaptive in content. In contrast, the PPI-R helps to detect both the largely adaptive (e.g., superficial charm, social poise, adventure seeking), and largely maladaptive (e.g., poor impulse control, callousness, dishonesty) features of psychopathy. Although initially intended to identify psychopathic individuals in noncriminal settings, such as those in student, community, and business samples, the PPI-R has since been used extensively in a variety of forensic contexts. This entry reviews the construction and structure of the PPI-R and then discusses its reliability and validity.

Construction of the PPI and PPI-R

The PPI consisted of 187 self-report items arrayed in 1–4 Likert-type format (1 = *false*, 2 = *mostly false*, 3 = *mostly true*, and 4 = *true*). It was developed over the span of several years in the late 1980s. The initial focal constructs considered for inclusion in the PPI were derived from a comprehensive review of the clinical and research literatures on psychopathy, including the seminal writings of Hervey Cleckley, Benjamin Karpman, David Lykken, Robert Hare, Joan and William McCord, Marvin Zuckerman, and Herbert Quay.

PPI items were written to be accessible and understandable by a broad range of respondents. To enhance the likelihood that psychopathic respondents would be willing to endorse trait-relevant items, most PPI items were phrased to be socially normative. For example, a PPI item written to assess dishonesty (retained in the PPI-R) is “I tell a lot of ‘white lies,’” which assesses a dishonest action that is both mild and common in the general population. A PPI-R item written to assess grandiosity is “People are impressed with me after they first meet me,” which ostensibly assesses a feature of narcissism that is positively valued. In

the initial version of the PPI, approximately an equivalent number of items were keyed in the true and false directions to minimize acquiescence (“yea-saying”) and counter-acquiescence (“nay-saying”) response biases.

The PPI and PPI-R contain three validity scales designed to detect response biases that may be especially problematic among psychopathic individuals: Deviant Responding, Virtuous Responding, and Inconsistent Responding. Deviant Responding, intended to detect malingering and otherwise aberrant responding, consists of questions that assess largely or entirely nonexistent signs and symptoms of psychopathology (e.g., “I look down at the ground whenever I hear an airplane flying above my head”). Virtuous Responding (called *Unlikely Virtues* in the PPI), intended to assess positive impression management, consists of questions that assess denial of common frailties (e.g., “Every once in a while, I nod my head when people speak to me even though I’m not paying attention to them,” keyed in the false direction). Inconsistent Responding (called *Variable Response Inconsistency* in the PPI), intended to detect random or careless responding, consists of item pairs in which the items are moderately to highly correlated; numerous inconsistent responses to the items within each pair generate a high score. For example, 2 PPI-R items ask about fears of parachute jumping in slightly different ways, and respondents who provide markedly different answers to these items gain a point on the Inconsistent Responding Scale.

The PPI items and constructs were progressively refined by means of factor analyses on three successive undergraduate samples, with a total sample size of 1,156 participants. The eight lower order factors comprising the PPI emerged across three rounds of test development and provide a broad, although by no means comprehensive, portrait of the key affective and interpersonal features of psychopathy. These eight subscales are now termed *Social Influence* (formerly *Social Potency*), *Fearlessness*, *Stress Immunity*, *Machiavellian Egocentricity*, *Blame Externalization* (formerly *Alienation*), *Rebellious Nonconformity* (formerly *Impulsive Nonconformity*), *Carefree Nonplanfulness*, and *Coldheartedness* (see Table 1 for descriptions of each subscale).

Table 1 Description of PPI-R Scales

<i>Scale</i>	<i>Description</i>
<i>Fearless Dominance</i>	
Social Influence (previously <i>Social Potency</i>)	Perceived ability to influence and manipulate others
Fearlessness	Absence of anticipatory anxiety concerning harm and a willingness to participate in risky activities
Stress Immunity	Absence of marked reactions to anxiety-provoking events
<i>Self-Centered Impulsivity</i>	
Machiavellian Egocentricity	Narcissistic and ruthless attitudes in interpersonal functioning
Rebellious Nonconformity (previously <i>Impulsive Nonconformity</i>)	Reckless lack of concern regarding social norms
Blame Externalization	Tendency to blame others for one’s problems and to rationalize one’s misbehavior
Carefree Nonplanfulness	Attitude of indifference in planning one’s actions
Coldheartedness	Propensity toward callousness, guiltlessness, and lack of sentimentality
<i>Validity Scales</i>	
Virtuous Responding (previously <i>Unlikely Virtues</i>)	Positive impression management
Deviant Responding	Tendency to admit bizarre symptoms not indicative of known psychopathology
Inconsistent Responding	Tendency to answer related pairs of items in an inconsistent manner

The PPI was revised (to the PPI-R) in 2005 to reduce its length, decrease its reading level to make it more applicable to forensic (e.g., prison) samples, and eliminate items that were psychometrically suboptimal or that contained culturally specific idioms. Based on factor analyses of large

student/community and offender samples, a number of inadequately functioning PPI items were eliminated or revised. In addition, the PPI-R manual provided age- and gender-specific norms for general population (student and community) and offender samples. The PPI-R consists of 154 items divided into the same subscales and three validity scales as the PPI.

Higher Order Factor Structure of the PPI-R

Factor analyses of the PPI-R subscales have often yielded a coherent three-factor structure. Nevertheless, because the PPI and PPI-R were not developed to yield a clear higher order factor structure, this structure does not emerge unambiguously in all samples. In contrast to the factors of most psychopathy measures, those of the PPI-R are largely orthogonal (uncorrelated).

One higher order dimension, termed *Fearless Dominance*, consists of scores on the Social Influence, Fearlessness, and Stress Immunity subscales. This dimension appears to assess a broad trait that Florida State University psychologist Christopher Patrick and his colleagues term *boldness* that encompasses social and physical risk-taking, interpersonal poise, emotional resilience, and calmness in the face of stressors. More generally, Fearless Dominance may assess the largely adaptive features of psychopathy that sometimes predispose individuals to success in business, politics, high-risk sports, and other life domains.

A second higher order dimension, termed *Self-Centered Impulsivity*, consists of scores on the Machiavellian Egocentricity, Blame Externalization, Rebellious Nonconformity, and Carefree Nonplanfulness. This dimension appears to assess a broad trait that Patrick and his collaborators term *disinhibition* that encompasses poor impulse control, recklessness, narcissistic ruthlessness, and perception of oneself as a victim. In contrast to Fearless Dominance, Self-Centered Impulsivity appears to assess the largely maladaptive features of psychopathy, placing certain individuals at risk of externalizing psychopathology, including criminal behavior and substance abuse. Not surprisingly, this dimension—in contrast to Fearless Dominance—tends to be highly correlated with measures of ASPD.

The PPI-R Coldheartedness does not load highly on either the Fearless Dominance or Self-Centered Impulsivity dimensions and is increasingly treated as a stand-alone dimension in analyses. This dimension appears to assess a trait similar to what Patrick and colleagues term *meanness*, although Coldheartedness tends to reflect passive emotional detachment rather than active antagonism. More than the other two PPI-R higher order dimensions, Coldheartedness tends to relate (negatively) to measures of affective empathy and guilt.

Reliability

The test–retest reliability of the PPI-R total score (across an average 20-day interval) in a general population sample is .93, which is very high; the test–retest reliabilities of the subscales are similarly high, ranging from .82 to .95. The internal consistency (Cronbach's alpha) of the PPI-R total score in the general population is also high (.92), and the internal consistencies of its subscales range from .78 to .87. Nevertheless, the high Cronbach's alpha for the total score conceals the fact that the average inter-item correlations for the PPI-R total score tend to be low (below $r = .10$), consistent with the substantial heterogeneity of PPI-R-assessed psychopathy.

Validity

A large body of literature across numerous samples, including college, community, and forensic samples, offers support for the construct validity of the PPI-R. For example, PPI-R total scores correlate moderately to highly with self-report, observer-based (e.g., peer ratings of psychopathy), and interview-based indices of psychopathy, as well as with indices of conditions that overlap with psychopathy, such as narcissistic and histrionic personality disorders. PPI-R total scores are also positively associated with measures of ASPD, although this association is sufficiently modest in magnitude to indicate that the PPI-R distinguishes psychopathy from ASPD. Like most other psychopathy measures, PPI-R total scores relate in theoretically meaningful ways with several traits of the well-accepted five-factor model of personality, especially Agreeableness and Conscientiousness (both

negatively). In addition, PPI-R total scores are positively correlated with a broad spectrum of personality traits theoretically tied to psychopathy, such as sensation seeking, interpersonal dominance, grandiose narcissism, impulsivity, and Machiavellianism. Just as important, PPI-R total scores display discriminant validity from measures of constructs that are theoretically separable from psychopathy, such as indices of schizophrenia spectrum disorders, depression, and social desirability.

The PPI-R higher order dimensions display encouraging validity as well. For example, Fearless Dominance tends to be modestly and negatively associated with laboratory measures of fear processing, such as fear-potentiated startle and amygdala activation in response to fear-provoking stimuli, and Self-Centered Impulsivity tends to be positively associated with ventral striatum activation in response to reward-related cues. In addition, Fearless Dominance differentiates psychopathy from ASPD, consistent with the view that the former condition tends to be associated with somewhat more psychologically adaptive traits than the latter.

Nevertheless, the role of Fearless Dominance within the psychopathy construct is controversial. Some authors contend that Fearless Dominance is largely or entirely irrelevant to psychopathy given that it is seemingly adaptive in content and only weakly associated with measures of antisocial and criminal behavior. Along these lines, some authors have questioned or rejected the possibility that certain psychopathic traits can predispose to adaptive outcomes in certain contexts, such as the business or political worlds. In contrast, other authors, ourselves included, regard Fearless Dominance as a key feature of psychopathy given that it accounts largely for the superficial charm, poise, and venturesomeness captured in classic clinical descriptions of the condition, such as those of Cleckley. Interestingly, Fearless Dominance correlates moderately to highly with scores on some psychopathy measures but not others, suggesting that different psychopathy measures differ sharply in their conceptualization and operationalization of this condition. Specifically, some psychopathy measures may be slanted largely toward successful variants of psychopathy, whereas others may be slanted largely toward unsuccessful variants, such as those linked to ASPD.

PSYCHOPATHIC TRAITS, STRUCTURE OF

Psychopathy is a disorder conceptualized as a constellation of inherently dissocial personality and behavioral characteristics. Early thinkers have been instrumental in initial conceptualizations of psychopathy, particularly Hervey Cleckley, who has played a large role in shaping the understanding of this construct. However, despite providing an influential clinical profile, Cleckley's contribution was based on case studies and did not offer an empirical assessment method or a parsimonious conceptualization. To address the diagnostic confusion pervading the field, Robert D. Hare developed the Psychopathy Checklist (PCL) and subsequently the PCL–Revised (PCL-R), a standardized interview to assess psychopathy in a manner consistent with Cleckley, other theorists, and Hare's own research.

The PCL-R is a 20-item construct rating scale that conceptualizes psychopathy as a dimensional, superordinate construct consisting of four dimensions (or factors). These dimensions are

- *interpersonal* (superficial charm, grandiose sense of self-worth, pathological deception, and manipulative),
- *affective* (lack of remorse or guilt, shallow affect, callousness and lack of empathy, and failure to accept responsibility),
- *lifestyle* (need for stimulation, parasitic lifestyle, lack of realistic long-term goals, impulsivity, and irresponsibility), and
- *antisocial* (poor behavioral controls, early behavior problems, juvenile delinquency, revocation of conditional release, and criminal versatility).

Each PCL-R item is rated on a 3-point scale (0 = *absent* to 2 = *present*) with a 20-item total score of 30 or above used as a diagnostic indicator for psychopathy. However, as psychopathy varies continuously, the cutoff is used primarily for research purposes or forensic decisions. Derivatives of the PCL-R (e.g., PCL: Screening Version, PCL: Youth Version) are anchored in the same theoretical network and are collectively referred to as the *PCL scales*. Once the PCL provided a common metric for the field, psychopathy research has accumulated at a rapid pace. This entry provides an overview of the structure of psychopathy in the PCL scales.

Studying the Structure of Unobservable Variables

The idea that understanding a phenomenon's form gives insight into its function is a line of scientific inquiry found in psychological science as well as other disciplines (e.g., genetics, physics). In psychology, the phenomena studied are hypothetical constructs, because they are not directly observable. For instance, when individuals engage in adaptive behavior, it may be suggestive of intelligence. Their actions serve as indicators of their underlying unobservable intellectual potential. With the advent of structural equation modeling and item response theory, researchers could mathematically represent unobservable (latent) constructs. Observed (manifest) variables (e.g., behavioral observations, self-reported personality traits) are assessed across large samples, and the variance and associations among the manifest variables are accounted for by underlying latent variables (factors). These statistical methods allow

researchers to propose and statistically test structural model specifications (e.g., variable-to-factor and factor-to-factor relations) that correspond to the theoretical nature of a phenomenon.

Although latent variable models may demonstrate good statistical fit, the models and observed measures used to represent the structural features of psychological constructs should not be confused with the hypothetical constructs. However, as the models involve testable hypotheses, good model fit can serve as supportive evidence. Additionally, if a latent variable model is independently replicated using diverse samples and assessment methods, the model's veracity increases as a viable representation of the construct. Two overarching goals of latent variable modeling are to provide viable mathematical models of psychological constructs aligned with theory and to provide models that offer a parsimonious accounting of a larger set of variables. Therefore, if a model does not represent a vital aspect of a construct, or is as complex as the data it proposes to account for, then such models have little utility in advancing the understanding of psychological constructs. Using these methods, Hare, Craig Neumann, and their colleagues have worked to uncover the structure of psychopathy.

Two-Factor Model of Psychopathy

Initially, a two-factor model of psychopathy was heavily utilized in studies employing PCL-derived scales. Validated using exploratory factor analysis in a large sample of criminal offenders and forensic inpatients, the two-factor model integrates the personality and behavioral characteristics of psychopathy. Factor 1 (F1) encapsulates the interpersonal and affective characteristics of psychopathy, whereas Factor 2 captures the lifestyle and antisocial features. However, this model has limitations. The inability of this model to be replicated using confirmatory factor analysis, a specific application of structural equation modeling and a more stringent hypothesis-based statistical procedure, and the identification of differential relationships between the four dimensions and external variables (e.g., intelligence, violence) indicated that the two-factor model needed refinement. Another issue of the two-factor model raised by investigators is the role of overt antisociality. Some

researchers suggested that the PCL-R focus on antisocial feature (e.g., juvenile delinquency, criminal versatility) drifts from Cleckley's conceptualization of psychopathy. Scott Lilienfeld proposed another two-factor model of psychopathy in his measure, the Psychopathic Personality Inventory, to address this drift. However, in addition to being developed in a population with very low prevalence of psychopathy (college students), the Psychopathic Personality Inventory, when subjected to latent variable modeling, shows very poor fit and no evidence for a two-factor model.

Three-Factor Model of Psychopathy

As a proposed refinement of the construct, some researchers attempted to model the PCL scales in terms of three factors. In this model, F1 is broken into two factors, arrogant and deceitful interpersonal style and deficient affective experience. A third factor, impulsive and irresponsible lifestyle, captures the lifestyle traits associated with psychopathy. These three factors are nested under a superordinate psychopathy factor. Further, all antisocial items were removed, reducing the PCL-R to 13 items. However, this model technically involves more than three factors and results in fundamental modeling errors. Specifically, instead of modeling the 13 items directly onto three factors, the researchers specified testlets (groupings of theoretically similar items) in terms of their own respective (first-order) factors. In this model, one begins by modeling the 13 PCL-R items onto one of six testlets (factors), which serve as indicators for three (second-order) factors, which are accounted for by a superordinate (third-order) psychopathy factor. Thus, it is a 10-factor model, which is nearly as complex as the 13 items the model attempts to account for. Although this model appears to demonstrate good fit, it is actually a misspecified model, which results in impossible model parameters (negative variances) due to overfactoring.

Another critical limitation of the three-factor model involves the subjective decision to omit certain items from the PCL. Specifically, it is questionable whether omitting antisocial items represented a more pure distillation of psychopathy, given findings from behavioral genetics, developmental studies, and modeling research.

Furthermore, it can be argued that the interpersonal and affective features of psychopathy are antisocial in nature, albeit covertly, as opposed to the overt antisociality that the three-factor model proponents attempted to disregard.

Four-Factor Model of Psychopathy

Although three-factor model proponents claimed that the PCL-R antisocial items are not consistent with traditional conceptions of psychopathy, Cleckley and other theorists (e.g., Silvano Arieti, Benjamin Karpman) have highlighted overt antisociality in clinical profiles of psychopathy. In critiques of the three-factor model, Hare, Neumann, and colleagues cited longitudinal and behavioral genetic studies that documented that antisocial behavior has a fundamental and bidirectional relationship with core psychopathic features (i.e., F1), due to the fact that it is a component of a general genetic factor that also accounts for other psychopathic traits. Further, Hare and colleagues demonstrated that the discarded items could be modeled as an overt antisocial factor with the three other factors, creating a four-factor model. In contrast to the two-factor model, the four-factor model specifies each underlying dimension as a separate factor. Unlike the three-factor model, which requires 10 factors, the four-factor model uses 18 of the 20 PCL-R items, and they load directly onto one of the four psychopathy factors. The four-factor model is a mathematically riskier model to test because it uses relatively fewer model parameters to account for more observed data. Moreover, strong intercorrelations among the four factors are accounted for by the presence of a superordinate psychopathy factor, which demonstrates that all four factors provide a comprehensive representation of the syndrome of psychopathy.

The four-factor model has good model fit across a variety of samples (e.g., forensic and civil psychiatric patients, adult and adolescent offenders, and large community and workplace samples). Additionally, the four-factor model has been found for self-report measures derived from the PCL scales such as the Hare Self-Report Measure of Psychopathy and the B-Scan 360, self-report measures of psychopathy for community and corporate settings, respectively. Further, using a

mega-sample of 33,000 participants from 11 major world regions, as well as an aggregate sample of over 52,000 individuals, the four-factor model had excellent fit across cultures and gender, irrespective of the nature of the PCL-derived scale being used (e.g., interview, self-report). In essence, the model holds up well across diverse samples of individuals and assessment methods, providing support for the verisimilitude of the four-factor model.

Although the three- and four-factor models cannot be directly compared because they use different numbers of items from the PCL scales, researchers have examined how well they predict important external correlates. When compared to the two- and three-factor models, the four-factor model did better in predicting instrumental aggression and violence, with the interpersonal, affective, and antisocial factors playing significant respective roles. These findings illustrate that both the covert and overt antisocial features of the construct are critical and illustrate the importance of viewing psychopathy as a disorder of both personality and behavior imbued with fundamental dissociality. Additionally, as the four-factor model parses psychopathy in terms of four correlated (first-order) factors under a superordinate psychopathy factor, it provides a model for understanding how psychopathic personality can be manifested in a variety of different profiles of the four factors. This represents a person-centered approach, which is being pursued in new research by Neumann and Hare.

Other Potential Structural Models

One final structural model to briefly mention is the bifactor model, which involves bifurcating the variance of items in terms of a general factor (which accounts for the variance of all items) and several specific factors (which are set to be uncorrelated with the general factor) that account for the variance of subsets of items. It is an easy model to fit to the data, given it requires a large number of factors. However, the challenging aspect of this model involves the interpretation of the specific factors. In this model, all of the PCL-R items are accounted for in terms of a broad general factor, which may represent the syndrome of psychopathy. However, since the specific factors are set to be uncorrelated with the general factor, it remains

unclear as to how one interprets the specific factors which in theory reflect aspects of psychopathy but are not related to the broad syndrome (i.e., the general factor) of psychopathy.

Implications and Future Directions

Latent variable modeling has allowed researchers to develop and test models about the underlying structure of psychopathy. Although the two-factor model provided an equal emphasis on personality and behavior, the lack of sophistication and statistical integrity led researchers to propose refinements. The three-factor model of psychopathy indicated that there was value in dividing F1 into factors reflecting interpersonal and affective features of psychopathy. However, the omission of antisocial items in the three-factor model led to substantial limitations. The four-factor model is the only model that has been replicated across large diverse samples with a variety of PCL-based scales. Moreover, the four-factor model has shown efficacy in predicting important external correlates associated with psychopathy, better than competing models.

All mathematical models are tools, however, and thus should not be confused with the construct they attempt to represent. Additionally, the majority of the research described is cross-sectional, and causality cannot be inferred from the models. Future research should incorporate longitudinal designs in examining the structure of psychopathy. Furthermore, future research should compare the utility of the models in predicting external correlates of psychopathy (i.e., recidivism, cognition) and how psychopathy can be manifested in terms of a variety of personality profiles.

PSYCHOPATHY

Psychopathy is a concept that carries strong connotations of *evilness* and *dangerousness*. In media and popular science, *the psychopath* is commonly portrayed either as a brutal mass murderer or as a vicious boss. Descriptions of individuals with clear psychopathic traits can be found in ancient literature, and clinical descriptions of psychopathic inpatients trace back to the 18th century. Psychopathy is an important personality construct in the forensic field, and psychopathy assessments are extensively used to inform legal decisions in North America and throughout Europe.

This entry describes the leading definitions and assessments of psychopathic traits, in both criminal and noncriminal settings. Psychopathic traits in childhood and adolescence are discussed with reference to causal theories. Also included are sections on the use of psychopathy assessments for legal decision-making purposes and on past and recent approaches to treatment of psychopathic offenders.

Conceptualization and Assessment of Psychopathy

Historical Overview

In the early 19th century, French psychiatrist Philippe Pinel described inpatients who repeatedly

engaged in violent and reckless behavior, despite appearing rational and mentally sound. According to Pinel, this peculiar psychiatric condition was characterized by *insanity without delirium*. Toward the end of the century, in the era of early psychiatric classifications, German psychiatrist Julius Ludwig August Koch proposed the term *psychopathic personalities* to characterize a relatively broad spectrum of conditions (e.g., mental retardation, neurotic conditions, so-called character disorders) that he believed had a biological basis. Although these early clinical accounts are less specific than contemporary definitions of psychopathy, they provide an illustration of how psychopathic individuals were seen to differ from other psychiatric inpatients.

American psychiatrist Hervey Cleckley's book *The Mask of Sanity*, first published in 1941, marks the first milestone in the modern conceptualization of psychopathy. The book contains 15 detailed case descriptions drawn from hundreds of patients seen by Cleckley at the University of Georgia's Medical Hospital. Based on salient features evident in these various cases, Cleckley formulated 16 clinical criteria for psychopathy, which encompassed not only features of emotional disturbance (e.g., shallow affect, lack of insight, deceitfulness) and behavioral deviance (e.g., failure to learn by experience, irresponsibility, promiscuity) but also some ostensibly adaptive features (e.g., superficial charm, absence of irrational thinking and nervousness, low propensity for suicidal behavior). In essence, Cleckley viewed psychopathy as a contradictory condition in which afflicted individuals appear rational and well functioning on the surface; however, over time, the *mask* of normality cleaves to reveal a deep-seated emotional disturbance and irresponsible, self-centered, and *aimless behavioral deviancy* (e.g., lying, stealing, forging checks). In contrast with accounts of criminal psychopathy from Cleckley's time to the present, it is worth noting that few of the psychopathic patients that he described were overtly aggressive or violent.

Cleckley's clinical criteria influenced the diagnostic descriptions of personality disorders in the first and second editions of the American Psychiatric Association's reference book for psychopathological conditions: the *Diagnostic and Statistical Manual of Mental Disorders* (DSM-I and DSM-II).

In line with Cleckley's conceptualization, the diagnostic criteria for conditions labeled *sociopathic personality disturbance antisocial reaction* and *antisocial personality* in these early editions of the *DSM* included distinct personality features (e.g., callousness, selfishness, absence of remorse or shame). In the third edition of the *DSM* (*DSM-III*), however, the corresponding diagnosis of antisocial personality disorder (ASPD) was largely based on observable deviant behaviors including destructive and delinquent acts (e.g., physical cruelty, vandalism), while excluding several of the personality-oriented criteria identified by Cleckley (e.g., superficial charm, lack of anxiety).

These revisions to the diagnostic criteria within the *DSM-III* were influenced by two factors in particular. One is that personality features were considered difficult to score in a reliable manner at that time. A second factor was the strong emphasis placed on behavioral indicators of antisociality in the highly influential work of psychiatric epidemiologist Lee Robins in the 1970s, focusing on developmental aspects of *sociopathy* in delinquent youths. The ASPD diagnosis as formulated in the *DSM-III* has remained essentially the same in subsequent editions of the manual (i.e., *DSM-IV* and *DSM-5*).

In the *DSM-5*, criterion-based definitions of ASPD and other personality disorders, equivalent to those in the *DSM-IV*, are included in Section II ("Diagnostic Criteria and Codes"). An alternative dimensional-trait system for personality disorders appears in Section III ("Emerging Measures and Models"). In this alternative system, ASPD is defined by high levels of disinhibitory and antagonistic traits and includes a *psychopathy specifier* for denoting the presence of distinct traits indicative of low-anxious, socially dominant (primary psychopathic) variant of ASPD. As such, the *DSM-5* Section III definition captures key features of psychopathy that have been emphasized both in historic writings and in contemporary research work (as described next), but absent from ASPD as defined in the *DSM-III* and the *DSM-IV*.

Contemporary Conceptualizations of Psychopathy

In contrast to ASPD, psychopathy encompasses interpersonal-affective (i.e., charming-manipulative

and callous-exploitative) traits along with impulsive-antisocial (i.e., disinhibitory-externalizing) tendencies. The most widely used rating scale for assessing psychopathy is the Psychopathy Checklist-Revised (PCL-R). The PCL-R was developed for use with correctional and forensic populations and has been used with both male and female offenders.

The PCL-R assesses psychopathy in terms of 20 items, each scored 0–2 on the basis of information derived from a face-to-face interview and institutional file records. The suggested cutoff for psychopathy is a PCL-R total score of 30 in the North American context, with slightly lower thresholds in some European countries. The predecessor to the PCL-R, the 22-item PCL, was formulated partly based on a global rating protocol that reflected Cleckley's clinical conceptualization. However, in the process of selecting and refining items for the PCL, adaptive features in Cleckley's conceptualization (e.g., absence of nervousness) were omitted. Consequently, the PCL-R items strongly emphasize deviant and criminal behavior. The PCL-R has several alternative versions, including the Psychopathy Checklist Screening Version, a briefer screening protocol suited for assessment contexts in which file information is lacking (e.g., psychiatric inpatients, community groups).

There is an asymmetric overlap between ASPD as defined in the *DSM-5* Section II and psychopathy as assessed by the PCL-R: Most individuals who qualify for a PCL-R diagnosis of psychopathy also meet criteria for ASPD; however, the reverse is not true (i.e., only a portion of individuals with ASPD also meet criteria for psychopathy). Highlighting this, the estimated prevalence of ASPD in correctional populations is 50–80%, with the corresponding figure for psychopathy being 15–25%. The PCL-R encompasses two broad factors that show contrasting correlates with various external criteria (e.g., trait-dispositional, behavioral, physiological, clinical). The affective-interpersonal Factor 1 (F1) demonstrates positive associations not only with maladaptive tendencies of certain types (e.g., narcissism, thrill seeking, instrumental aggression) but also with some adaptive criterion measures (e.g., verbal ability, social assertiveness, emotional resiliency). The lifestyle-antisocial Factor 2 (F2), however, is predominantly associated with adverse outcomes (e.g., stimulation seeking, impulsivity,

aggressiveness, alcohol and drug problems). The two PCL-R factors can be further subdivided into narrower facets (interpersonal, affective, impulsive-irresponsible, antisocial) that show distinctive correlates.

The Comprehensive Assessment of Psychopathic Personality–Institutional Rating Scale was developed as an alternative interview-based measure for use in correctional and clinical settings. The scale indexes psychopathy in terms of trait tendencies within six domains: *Attachment, Behavioral, Cognitive, Dominance, Emotional, and Self*. The Comprehensive Assessment of Psychopathic Personality symptoms can be assessed over differing time frames, ranging from past 6 months to lifetime.

Dimensional Psychopathic Traits and Self-Report Measures

In early clinical accounts and in previous editions of the *DSM*, psychopathy and ASPD have been conceptualized as discrete clinical *syndromes*. Psychopathy assessments are commonly used in current applied and legal contexts to generate statements regarding whether an individual meets criteria for psychopathy or not. During the 2000s, however, researchers have increasingly moved away from the position that psychopathy represents a discrete category. There is now strong consensus that psychopathic traits are dimensional (i.e., that individuals can have psychopathic traits to different degrees) and can be assessed in the population at large. Even though psychopathy was mainly investigated in criminal groups up until the 1990s, research on psychopathic traits in clinical and community groups has increased substantially. Investigating psychopathic traits in dimensional terms provides opportunities to gain improved understanding of how differing constellations of traits develop, manifest, and progress over time. Such research can provide insight in how different configurations of psychopathic traits are associated with behavioral (e.g., impulsivity, decision-making) and physiological variables (e.g., reactivity to fear cues and punishment).

Different self-report measures have been developed for assessing psychopathy as a dimensional construct outside of criminal settings, including the Levenson Self-Report Psychopathy Scale, the

Hare Self-Report Psychopathy Scale, the Psychopathic Personality Inventory–Revised (PPI-R), the Triarchic Psychopathy Measure (TriPM), and the Elemental Psychopathy Assessment.

The different instruments for assessing psychopathic traits are based on theories of psychopathy that converge to a substantial extent; however, they also diverge to some degree. For example, in contrast to the Hare Self-Report Psychopathy Scale, the PPI-R does not include items directly referencing antisocial behavior, and it includes some *semi-adaptive* traits (e.g., fearlessness, stress immunity) emphasized in Cleckley's description. A common or definite conceptualization of psychopathy is still lacking, and several points are still debated, including the following: (a) whether psychopathy encompasses semi-adaptive features, (b) whether antisocial and criminal behavior should be included in the mere definition of psychopathy or rather be considered potential consequences of psychopathic traits, (c) whether lack of anxiety is inherent to psychopathy, and (d) whether there are different subtypes of psychopathy.

Psychopathic Traits in Childhood and Adolescence

In line with theoretical models for psychopathy in adults, research has demonstrated that psychopathic traits in children and adolescents encompass three distinct components: affective, and interpersonal, features (e.g., callousness, remorselessness, grandiosity, manipulative behavior) along with impulsive-behavioral tendencies (e.g., irresponsibility, impulsiveness, thrill seeking). Elevated psychopathic traits in youths have been associated with various adverse outcomes (e.g., cruelty, substance misuse, aggressive and violent behavior). Different instruments exist for assessing psychopathic traits in youth, including the interview-based Psychopathy Checklist: Youth Version, which is a direct counterpart to the PCL-R, and the informant- (i.e., parent- or teacher-) rated Antisocial Process Screening Device and Child Psychopathy Scale. Self-report instruments also exist for assessing psychopathic traits in older children and adolescents, including questionnaire versions of the Antisocial Process Screening Device, Child Psychopathy Scale, the Youth

Psychopathy Traits Inventory, and the Inventory of Callous-Unemotional Traits. There has been extensive interest since the mid-1990s in investigating callous-unemotional (CU) traits as a childhood precursor to core psychopathic traits in adulthood. Research has demonstrated that youths with conduct disorder (CD) who exhibit CU traits have distinct cognitive and affective impairments relative to those lacking in CU traits, and they present with elevated levels of aggression and more severe antisocial-delinquent behavior. For example, high levels of CU traits are associated with aberrant processing of fear- and punishment-related cues and also pain and distress in other people. This deviant affective processing is theorized to hinder the development of prosocial behavior and hence operates as a precursor to deficient lack of empathy and guilt. Research evidence indicates that CD with and without CU traits may have different etiological underpinnings and prognostic implications. CU traits appear to be moderately to strongly heritable, and it has been suggested that this symptom component is more stable over time than the impulsive-antisocial component and thus constitutes a key vulnerability factor for psychopathy in adulthood.

Associations between psychopathic traits in youth and adult psychopathy remain unclear, however. The stability of psychopathic traits in general, and CU traits specifically, over longer time periods remains unclear. Advanced research designs are needed to clarify developmental trajectories of early psychopathic tendencies and how genetic factors relate to and interact with differing environmental factors (e.g., family influences, peer influences, socioeconomic status, neighborhood factors). Improved understanding in these areas may have important implications for treatment and intervention. In this regard, it is notable that the diagnostic criteria for child CD were revised in the *DSM-5* to include a *limited prosocial emotions* specifier for designating a *psychopathic* variant of CD entailing the presence of salient CU traits. This change sets the stage for increased research along lines needed to advance what is known about the expression and stability of CU traits.

Etiology of Psychopathy

Considerable research has been devoted over many years to investigating causal factors in psychopathy.

Existing theories are of two types: (1) theories emphasizing core deficits in emotional sensitivity or responsiveness (e.g., low fear) and (2) theories positing impairments in cognitive-attentional processing (e.g., impaired set shifting). Differing neurobiological correlates of psychopathy have been reported as support for these alternative theories. One of the most consistent involves a lack of normal enhancement of the startle blink reflex to acoustic probes presented during viewing of aversive foreground stimuli (e.g., scary or disturbing pictorial images) as compared with neutral or pleasant stimuli. This result, akin to a failure to *jump* upon hearing an unexpected noise while walking alone in a dark alley, has been interpreted as reflecting a lack of normal defensive (fear) reactivity. Another consistent finding involves reduced amplitude of cortical brain response to intermittent target stimuli, or following incorrect responses, in cognitive performance tasks—indicative of reduced cortical-attentional processing or impaired action monitoring. Yet other research using functional neuroimaging has demonstrated deficits in basic subcortical (amygdala) reactivity to interpersonal distress cues (e.g., fearful human faces) in individuals high on psychopathy.

As noted earlier, psychopathy encompasses differing symptomatic facets, and these facets show contrasting associations with physiological response indicators. For example, affective-interpersonal symptoms are associated with lack of aversive startle potentiation, and impulsive-antisocial symptoms are associated with reduced cognitive brain response. Dating back to work by David T. Lykken in the 1950s, there is also evidence for distinct subgroups of individuals high on psychopathy who differ in emotional reactivity: *primary psychopaths*, who show antisocial tendencies in conjunction with *deficient emotion* (in particular, lack of fear), and *secondary psychopaths*, who show antisocial tendencies in conjunction with *emotional dysregulation* (i.e., intense hostility and negative affect). Consistent with this perspective, research during the 2000s with both correctional samples and community groups has yielded evidence for two distinct subtypes of individuals high in overall psychopathy, distinguished in particular by low versus high scores on measures of negative emotionality (e.g., anxiety, depression, somatization). It is hypothesized that different etiological pathways might underpin these subgroups.

Weaknesses in emotional response systems appear to contribute especially to core affective-interpersonal features of psychopathy and perhaps to the *primary* subtype of psychopathic individual. Deficits in cognitive processing systems appear to contribute more to impulsive-antisocial features of psychopathy and perhaps to the *secondary* psychopathic type. A formal theoretic conceptualization that has been proposed to account for differing symptomatic (phenotypic) expressions of psychopathy, and causal sources contributing to these differing expressions, is the triarchic model.

Triarchic Model of Psychopathy

The triarchic model conceives of psychopathy as encompassing three separable symptomatic components—disinhibition, boldness, and meanness—that can be viewed as thematic building blocks for differing conceptions of psychopathy. *Disinhibition* encompasses tendencies toward impulsiveness, weak behavioral restraint, hostility and mistrust, and difficulties in regulating emotion. *Meanness* entails deficient empathy, lack of affiliative capacity, contempt toward others, predatory exploitativeness, and empowerment through cruelty and destructiveness. Referents for disinhibition and meanness include the finding of distinct Impulsive/Conduct Problems and CU symptom components in the child psychopathy literature and corresponding evidence for distinct disinhibitory and callous-aggression factors underlying impulse control (externalizing) problems in adults. The third triarchic construct, *boldness*, encompasses dominance, social assurance, emotional resiliency, and venturesomeness. Referents for boldness include the *mask* elements of Cleckley's conception, the low fear theory of psychopathy, the affective-interpersonal factor of the PPI-R, and developmental research on fearless temperament as a possible precursor to psychopathy.

From the perspective of the triarchic model, Cleckley's conception of psychopathy emphasized boldness and disinhibition, whereas criminally oriented conceptions (and affiliated measures, including the PCL-R and Antisocial Process Screening Device) emphasize meanness and disinhibition more so. According to the model, individuals high in disinhibitory tendencies would warrant a diagnosis of psychopathy if also high in

boldness or meanness (or both), but individuals high on only one of these dimensions would not. Individuals with differing relative elevations on these three symptomatic dimensions would account for contrasting variants (subtypes) of psychopathy as discussed earlier.

A self-report instrument designed specifically to index the constructs of this conceptual model is the 58-item TriPM. The TriPM includes Disinhibition and Meanness scales derived from the Externalizing Spectrum Inventory, a questionnaire measure of problems and traits associated with externalizing psychopathology. The TriPM also includes a Boldness scale that indexes fearless tendencies in social-interpersonal, affective-experiential, and activity-preference domains. Although the TriPM is relatively new, promising evidence for its convergent and discriminant validity has begun to appear. In addition, considerable work has been done to establish scale measures of the triarchic model constructs using items from other existing psychopathy inventories including the PPI-R and the YPI.

The triarchic model may prove useful for reconciling alternative causal theories of psychopathy that have been proposed based on differing neurobiological and behavioral findings. For example, lack of startle enhancement during aversive cueing has been tied specifically to the interpersonal-affective factor of the PCL-R and the counterpart Fearless Dominance factor of the PPI-R—suggesting a link to the boldness component of psychopathy; by contrast, reduced brain potential responses in cognitive tasks appear more related to impulsive-externalizing tendencies associated with the disinhibition component of psychopathy. On the other hand, the finding of reduced subcortical response to affective facial cues has been tied to the CU traits factor of child/adolescent psychopathy, a referent for meanness in the triarchic model. However, further research is needed to determine whether this finding reflects fear deficits common to meanness and boldness or deficits in affiliative capacity or empathy specific to meanness.

Psychopathy and Applied Criminology

Legal Decision-Making

In North America and throughout Europe, psychopathy assessments are commonly used to

inform legal proceedings (e.g., regarding sentencing, parole) and decisions regarding institutional placement and surveillance. In the vast majority of cases, these assessments are conducted using the PCL-R or the PCL-Screening Version/Youth Version. The use of PCL-based psychopathy assessments in legal procedures regarding adult offenders in the United States has increased steadily since the 1990s and has also become relatively common in juvenile risk evaluations. Based on the well-established association between psychopathy and deviant behaviors, PCL-based psychopathy assessments are used to infer whether an individual has an elevated risk of criminal relapse or institutional misconduct. In some cases, PCL-based assessments are also used to exclude individuals from therapeutic intervention, based on preconceptions that psychopathy is untreatable. In some jurisdictions in North America, psychopathy assessments are specifically used to evaluate risk of sexual recidivism in so-called sexually violent predator cases or to inform decisions about indeterminate incarceration of *dangerous offenders*. Given this widespread use, increased information is needed regarding applied implications of PCL-R assessments (e.g., what cutoff levels are used and how total and factor scores are interpreted).

In risk evaluations, PCL-based psychopathy assessments have either been used individually or incorporated into instruments specifically designed to assess risk (e.g., the Historical-Clinical-Risk Management 20, the Violence Risk Appraisal Guide, and the Sex Offenders Risk Appraisal Guide)—although the PCL-R has been omitted as a requirement in the newest editions of some of these instruments (e.g., version 3 of the Historical-Clinical-Risk Management 20). In contrast with broader risk assessment protocols, the PCL-R itself does not encompass features that are empirically related to violence risk (e.g., substance abuse, psychiatric comorbidity). Moreover, the PCL-R items are scored based on lifetime occurrence; thus, the instrument is not suited to assessing changes following from interventions. Meta-analytic work has demonstrated comparable predictive validity for the PCL-R for future violence in comparison to risk-assessment instruments but lower predictive ability for sexual recidivism. Furthermore, accumulated research evidence indicates

that the predictive validity of the PCL-R is mainly due to its antisocial facet (reflecting past delinquent/criminal behaviors), with limited additional predictive value of its other facets.

Another issue that is important to consider is the interrater reliability of the PCL-R in clinical field settings (i.e., consistency of scores across raters when the same individual is assessed repeatedly). Field research conducted in different jurisdictions (i.e., United States, Canada, Sweden) has demonstrated acceptable interrater reliability for the largely objective criteria in the PCL-R's antisocial facet (e.g., number of previous offenses); however, markedly lower reliabilities have been found for the remaining facets reflecting interpersonal, affective, and impulsive-irresponsible traits. These findings highlight the need for caution in the use of PCL-R assessments in legal decision-making contexts and point to a need for research into ways for increasing the interrater reliability of PCL-R ratings in field and clinical settings.

In addition to the aforementioned shortcomings, the PCL-R assessments are labor-intensive, and their use is limited to institutionalized populations. Alternative self-report measures are often brief, easy to administer, and do not require additional training. Self-report measures have been criticized, however, on the grounds that psychopathic individuals lack insight into the nature and extent of their psychopathology and are prone to deceive and manipulate others. In particular, the vulnerability of such measures to response distortion and especially to faking good (i.e., the exaggeration of positive features and/or the minimization of negative features) raises concerns about the potential for false negatives (i.e., failures to detect psychopathy when present). This concern has been reinforced by research findings indicating that individuals high on psychopathy can successfully lower their scores on self-report psychopathy measures and that social desirability/faking good is negatively correlated with scores on various psychopathy scales. Even the use of validity scales, designed to detect dissimulation in responding, does not provide for adequate detection of deception on report-based psychopathy scales. Although such response biases do not necessarily compromise the validity of self-report psychopathy measures in research settings, and psychopathic individuals may not be as skilled in deceiving as

often assumed, caution is still warranted in using self-report measures of psychopathy in settings (e.g., legal contexts) where respondents might have clear incentives to fake good.

Forensic Treatment

A long-standing view among both clinicians and researchers has been that psychopathic individuals are unchangeable and hence untreatable. This pessimistic view dates back at least to Cleckley, who argued that no treatment program could achieve fundamental changes in a psychopathic individual. Some empirical studies conducted in the 1990s on treatment of psychopathic offenders drastically fueled this pessimistic view. One of these studies examined the impact of an intensive therapeutic program on incidents of criminal and violent recidivism assessed over an average follow-up period of 10 years. The results indicated that psychopathic offenders—in contrast with nonpsychopathic offenders who showed reductions in violent and overall recidivism following treatment compared to matched untreated controls—showed relative *increases* in reoffense rates. The authors interpreted these results as indicating that the treatment program led psychopaths to become more skilled in their ability to manipulate and exploit others.

A subsequent study corroborated this finding—demonstrating that forensic patients with elevated PCL-R scores who exhibited positive responsiveness to treatment (e.g., motivation to participate, in-session compliance, positive change ratings) were more likely to reoffend following release than patients with lower PCL-R scores who received treatment or untreated patients. Other studies have indicated that PCL-R scores are related to disruptive behavior in treatment, higher dropout rates, and negative therapist perceptions of motivation and progress in treatment.

Understandably, the main findings from these empirical studies perpetuated the belief among clinicians and researchers that psychopathy is essentially untreatable. However, important criticisms have been leveled against these investigations. The study examining outcomes of the intensive therapeutic program, for example, has been criticized for the radical, punitive, intrusive, and unethical nature of the treatment program

that was used. A subsequent reanalysis that evaluated reoffending during a longer follow-up period using an improved method for quantifying recidivism rates concluded that there was in fact no evidence that offenders high on psychopathy who exhibited positive treatment behavior reoffended at greater rates than other offenders.

Although research conducted during the 2000s suggests that psychopathic individuals typically do not respond positively to standard treatment interventions administered in mental health or justice settings, there are indications that intensive treatment interventions tailored to the emotional, cognitive, and motivational styles of individuals with psychopathic traits can be effective. Three types of treatment programs can be distinguished, each focusing on a different outcome: (1) reducing criminal behavior, (2) targeting underlying mechanisms of psychopathy, and (3) reducing level of psychopathic traits.

Treatment programs that focus on reduction of risk of future violence and other criminal behaviors have shown evidence of effectiveness with adult and juvenile offenders high on psychopathy. For example, published studies suggest that psychopathic offenders who complete an intensive specialized treatment program are less likely to be reconvicted for sexual or other violent offenses and that in cases where recidivism occurs, it tends to involve less serious offenses compared to pretreatment.

Treatment programs focusing on the core deficits of psychopathy have the potential benefit of being tailored to the unique needs of both youth and adults with psychopathic traits. For example, a study focusing on children and adolescents randomly assigned either to a typical parental training intervention or an emotional-recognition training group demonstrated that children with elevated CU traits who received training in accurate perception and interpretation of emotions of others showed greater improvements in affective responding compared to those in the typical parent training group. Other recent work has examined whether affective-attentional impairments in adult offenders high on psychopathy could be altered through cognitive remediation training. Specifically, offenders scoring high in psychopathy were offered a training to remedy their lack of attention to contextual information. Following

this training, the participants improved both on attention to contextual-specific trained tasks and on untrained tasks. Although findings from these studies are promising, it remains to be determined whether remediation of processing impairments such as these will lead to actual harm reduction (e.g., decrease of violent behavior).

A third treatment approach is to focus on reducing the level of psychopathic tendencies exhibited. However, research on the changeability of psychopathy traits remains scarce. Although prominent writers have argued that the personality structure of psychopathic individuals is largely unalterable, there are some indirect and direct indications that this position may be inaccurate. First, empirical work has challenged the idea that personality disorders in general are enduring and stable. For example, treatment has been shown to attenuate symptoms of severe disorders such as borderline personality. Second, some work has shown that interventions have the potential to alter core dispositions associated with psychopathy in youth (i.e., callous-unemotional, narcissistic, and impulsive traits).

Replication studies in larger samples, with the use of randomized controlled trials, will be needed to corroborate these more positive findings pertaining to treatment of psychopathic individuals.

PSYCHOPATHY, ETIOLOGY OF

Psychopathy is a clinical condition marked by interpersonal-affective characteristics (charm, manipulativeness, callous-exploitativeness) along with impulsive-irresponsible tendencies and persistent antisocial behavior. According to the triarchic model of psychopathy, the interpersonal-affective features are expressions of more basic dispositions termed *boldness* and *meanness*, whereas the impulsive-irresponsible tendencies reflect general proneness toward externalizing problems (*disinhibition*). Persistent engagement in antisocial activities is seen to arise from these basic dispositional tendencies operating jointly.

This entry covers what is known about causal influences contributing to psychopathy, using the triarchic model as a reference point. A synopsis of historical perspectives on etiology and evolutionary models is first provided, followed by a discussion of the genetic and environmental bases of psychopathy, the biological mechanisms contributing to it, and the developmental precursors of adult psychopathy.

Historical Ideas About Etiology

In 1976, American psychiatrist Hervey Cleckley theorized that the root cause of psychopathy is a general deficit in the capacity for emotional experience. Being unaware of this deficit on their part, psychopathic individuals learn to mimic the normal responses of others (including emotional reactions) in order to *blend in* and achieve desired goals, resulting in an outward *mask of sanity*. Benjamin Karpman, a contemporary of Cleckley, highlighted the importance of diagnostic subtypes in seeking to understand the causal bases of psychopathy. He distinguished between a *primary* subtype, presumed to be largely constitutional (heritable) in origin and entailing a core deficit in emotional sensitivity as hypothesized by Cleckley, and a *secondary* subtype, believed to arise more from adverse environmental influences and marked by excessive negative affect (anxiousness and hostility).

A 1957 study by David Lykken, considered the first empirical-laboratory investigation of psychopathy, tested the hypothesis that primary

psychopathic delinquents meeting Cleckley's criteria differed in emotional (specifically, anxiety or fear) reactivity from secondary psychopathic delinquents exhibiting impulsive-antisocial behavior but lacking in Cleckley's core features. More recent cluster analytic studies have confirmed the existence of subgroups of psychopathic offenders that differ markedly in negative affectivity.

Evolutionary Models

Three main evolutionary models have been proposed to account for the persistence of genes contributing to psychopathy. The *balancing-selection model* proposes that within the totality of genes contributing to psychopathy, there is a subset that promotes certain adaptive qualities that offset the negative selection pressure conferred by the maladaptive aspects of the condition—that is, Cleckley's *mask* features (superficial charm, low anxiousness and immunity to internalizing problems, disinclination toward suicide). A second evolutionary model is the *antagonistic-pleiotropy model*, which posits that certain genes contributing to the expression of psychopathy have both evolutionarily beneficial and detrimental effects. However, the genes that are beneficial—in particular, those that promote precocious and unbridled sexual activity—exert their effects earlier in life than those that are detrimental, resulting in a net gain in reproductive effectiveness. The third model, termed the *frequency-dependent model*, hypothesizes that genes associated with psychopathy will contribute maximally to adaptive fitness in societies where they are uncommon. Specifically, in societies where most people are trusting and accommodating, manipulative-exploitative individuals will be especially successful at surviving and reproducing. However, as the proportion of such individuals increases and awareness of their adverse impact on society grows, the survival advantage will diminish due to increased caution and societal protections against such behavior.

Although helpful for thinking about the origins and maintenance of psychopathic behavior in society, evolutionary theories are limited in important respects. For one thing, these models assume that variations in psychopathic tendencies are driven by natural selection, but direct evidence for this is lacking and potentially unattainable. In

addition, evolutionary models generally conceive of psychopathy as a unitary condition rather than a configuration of dispositional tendencies (i.e., boldness, disinhibition, and meanness, in triarchic model terms) that may have differing selective advantages and disadvantages.

Genetic and Environmental Influences

A growing literature has emerged on the role of genetic and environmental factors in psychopathy based on studies of monozygotic and dizygotic twins, who are presumed to share 100% and 50% of their genes, respectively—allowing for statistical estimation of sources of genetic and nongenetic influence in psychological characteristics. Twin research up through the 1990s focused on delinquent/antisocial behavior without consideration of core interpersonal-affective symptoms, yielding a limited picture of the etiology of psychopathy. Studies since the early 2000s focusing on psychopathic tendencies as a whole, assessed through self-report, have indicated heritability to be around 50%, with the remainder of variance attributable to nonshared (nonfamilial) environmental influences.

Other research has generated estimates for more specific subdimensions (facets) of psychopathy as described in the triarchic model. Studies focusing on the disinhibitory facet have yielded heritability estimates of around 80%. Initial work on the heritability of callous-unemotional traits (i.e., meanness) in young children suggested comparable heritability (~80%) for this facet of psychopathy. However, subsequent work indicates that this high heritability may characterize callous-unemotionality when accompanied by salient conduct problems (i.e., meanness plus disinhibition), with heritability lower for callous-unemotional traits per se (50–60%). Other twin work focusing on the boldness facet of psychopathy as assessed by self-report indicates heritability of around 50%.

In sum, available data point to moderate heritability for psychopathy scores as a whole, with distinctive facets of psychopathy exhibiting moderate to high heritability when examined separately. Of note, evidence for the high heritability of the disinhibitory facet challenges the notion that impulsive-antisocial behavior unaccompanied by salient affective-interpersonal features (i.e.,

so-called secondary psychopathy) is predominantly environmental in origin. Rather, it appears that there is a substantial heritability component to differing variants (subtypes) of psychopathy.

Biological Mechanisms

A number of theories have been advanced regarding biological mechanisms accounting for the observable symptoms of psychopathy. These can be grouped into two broad categories. One consists of theories that posit some underlying deficit in emotional reactivity, as suggested originally by Cleckley. Lykken presented the first experimental evidence that individuals meeting Cleckley's criteria were deficient in anxiety responses and later postulated that the various symptoms of psychopathy arise from a core deficit in fear reactivity. Other researchers have proposed that psychopathy entails an abnormally steep gradient of fear arousal or a weak behavioral inhibition (anxiety) system. Some have hypothesized that psychopathy results specifically from dysfunction in the amygdala, a subcortical brain structure involved in aversive learning and fear responding.

The other category consists of theories that postulate some sort of higher cognitive processing deviation. For example, Joseph Newman and his colleagues proposed during the 1990s that psychopathy involves a basic impairment in *response modulation*, defined as the ability to switch from an ongoing (dominant) action set to an alternative mode of responding when environmental cues signal the need for a shift. Similarly, other cognitive theorists have postulated a deficit in the ability to detect and respond to peripheral stimuli when attention is directed toward a high-priority ongoing task. Yet another view is that psychopathy involves a dissociation between semantic-denotative and affective-connotative aspects of language—such that high-psychopathic individuals are adept at saying the right things but without normal conviction or follow-through. This linguistic dissociation model of psychopathy intersects with affective-deficit theories.

An alternative to theories positing a single core deficit accounting for all symptoms of psychopathy is the possibility that different mechanisms contribute to its distinguishable subdimensions. Evidence for this comes from research demonstrating contrasting biological correlates for the

interpersonal-affective and impulsive-antisocial components of psychopathy and newer work documenting differential correlates for its boldness, meanness, and disinhibition facets. For example, a well-established correlate of the interpersonal-affective component is a lack of normal enhancement of the startle blink reflex to sudden noises presented during viewing of aversive visual images (e.g., frightening pictures) relative to neutral or pleasant images. This result indicates a lack of normal fear reactivity. Research with adults has shown this deficit to be associated specifically with the boldness facet of psychopathy.

Other work has shown that reduced brain potential response to target stimuli within cognitive performance tasks relates to the impulsive-disinhibitory component of psychopathy. This finding converges with a larger literature indicating impaired cortical-attentional responding in individuals with impulse-control problems more generally. Yet other research using functional neuroimaging has demonstrated deficits in amygdala reactivity to social distress cues (i.e., fearful human faces) in individuals scoring high on the callous-unemotionality (meanness) facet of psychopathy.

Taken together, these lines of evidence point to a role for more than just one type of biologically based processing deviation in psychopathy. Deficits in fear reactivity and impaired sensitivity to others' distress appear to be associated with the affective-interpersonal features of psychopathy (i.e., boldness and meanness, as described in the triarchic model), whereas reduced cortical-attentional processing appears to be associated more with its impulsive-disinhibitory features.

Developmental Processes

Child psychopathology research has identified distinct risk factors that are predictive of psychopathic tendencies across the life span. One important category of risk factors is subsumed by the notion of child temperament, referring to early emerging affective-behavioral tendencies presumed to have a strong basis in biology. The constructs of difficult temperament and fearless temperament are particularly relevant to psychopathy. Children exhibiting difficult temperaments tend to be irritable and easily distressed, high in activity, have problems adapting to novelty and change, and perform poorly in contexts requiring

sustained attention. This temperament profile is associated with increased risk of early conduct problems and conflictual interactions with caretakers and peers—and as such, can be seen as inherently related to the impulsive-disinhibitory facet of psychopathy.

Fearless temperament, marked by venturesomeness and low reactivity to unexpected events or stressors, has been described both as a dispositional substrate for boldness and an early risk factor for callous-unemotional traits. On one hand, a lack of normal fearfulness could operate to smooth social interactions and facilitate adaptive coping and thus contribute to successful outcomes. On the other hand, weak fear conditioning and affiliated deficits in behavioral inhibition could result in the impairments in conscience and punishment sensitivity observed in callous-unemotional children and psychopathic adults. As noted earlier, evidence for reduced sensitivity to aversive stimuli has been reported in relation to the affective-interpersonal features of psychopathy—both in terms of a lack of aversive startle potentiation (associated with bold tendencies in particular) and in terms of diminished reactivity to fearful face expressions (related to callous-unemotional [mean] tendencies especially).

However, deficits in early social attachment appear relevant to the interpersonal-affective features of psychopathy as well. For example, secure parent-child attachment, characterized by a developmentally appropriate balance of protectiveness and independence, has been shown to be predictive of positive outcomes across the life span. By contrast, insecure attachment can give rise to a defective internal working model of relationships, as evidenced by work showing insecure attachment to be more common in psychopathic offenders than other offenders. In particular, disrupted bonding—resulting from prolonged early separation from parents or deficits in parental care—is associated with higher psychopathy scores in adulthood. Other work indicates that child perceptions of parental relationship quality predict variations in callous-unemotionality, reflecting the importance of children's schematic understanding of interpersonal relationships. Importantly, child temperament may contribute in part to attachment strength. For example, children with difficult or fearless temperaments may pose greater rearing challenges that contribute to impaired parental relationships.

These lines of evidence highlight the importance of developmental processes and the complexity of forces that likely contribute to the emergence of psychopathic behavior across time. As opposed to one cause producing all symptoms, or separate specific causes accounting for distinct symptom facets, it seems likely that different causal factors contribute in interweaving ways to the observable symptoms of psychopathy—with alternative variants (subtypes) of psychopathy reflecting varying contributions of particular causal influences relative to others.

PSYCHOPATHY CHECKLIST (PCL)

The Psychopathy Checklist (PCL) is a research rating scale developed by Robert Hare and his colleagues for the assessment of the clinical construct of psychopathy in criminal populations. Before

the development of the PCL, the construct of psychopathy was well known to many mental health professionals, but determining what specific traits and behaviors contributed to a diagnosis was not easily established or agreed upon, making research into the construct difficult. The PCL, largely influenced by the clinical observations of American psychiatrist Hervey Cleckley, provides a list of personality and behavioral characteristics that are rated on presence and severity in the offender being assessed. Research was thus made possible into the construct of psychopathy. The PCL gave a quantifiable score and formed a common assessment measure that enabled research into psychopathy and its associated features. This entry discusses the historical context and rationale for developing the scale, details the components of the scale and how it is administered and scored, describes how the original PCL scale has evolved into a family of assessment measures for psychopathy, and then explores some of the early research studies that used the scale and influenced the course of psychopathy research. Lastly, some issues with the scale are explored, and how the PCL contributed to research and understanding of psychopathy is discussed.

Historical Context and Rationale for Developing the PCL

Individuals with psychopathic features have been observed in most societies over time. For example, Cleckley described the Athenian general Alcibiades from the 5th century as a psychopath who displayed reckless, treacherous, impulsive, and violent behaviors. Across different cultures, syndromes similar to psychopathy have been described. For example, the Yoruba, a rural tribe in Nigeria, use the term *Aranakan* to describe individuals who refuse to cooperate with others, who are bullheaded, and who are full of malice. The Alaskan Inuit use the term *Kunlangeta* to describe a man who refuses to go out hunting, who lies, who takes sexual advantage of women, and who does not respond to reprimands by elders.

Individuals with psychopathic traits are disproportionately represented in the criminal justice system. Those considered psychopaths (i.e., individuals who would score very high on the PCL)

represent approximately 1% of the general population, but in male offender populations, estimates range from 10% to 25%. Because individuals with psychopathic features have a significant influence on criminal justice system resources, the PCL has become an important assessment tool for this applied area of research.

Two observations largely influenced the development of the PCL as a research scale to assess psychopathy. First, theory and research on psychopathy were limited since no reliable and valid measure to assess the construct existed at the time. One measure of psychopathy that was often used was a global rating scale scored from 0 to 7. This scale was used to rate offenders on how much they represented the construct of psychopathy that was developed by Cleckley. Although this scale enjoyed good interrater reliability, the score was a single measure arrived at using clinical inference across all available information about the offender. Without clinical training, the global rating scale would be challenging for nonclinical raters to compile all the information of an offender into a single global score of psychopathy. A central purpose of the PCL then was to identify the features (i.e., traits and behaviors) that went into making the global ratings from the clinical inference and making a more objective measure that could assess the presence of those features. Thus, the PCL was a solution that could provide a common and more objective measurement accessible to clinical and nonclinical investigators researching and reporting on psychopathy.

The second observation that led to the PCL's development was a concern that clinical decisions about the assessment and diagnosis of psychopathy were being made with a limited focus on the offender's life. Diagnoses about psychopathy were often made based on the offender's current state without regard for the offender's past states. This may have created issues for the reliability and validity of a psychopathy diagnosis since the current state of an offender can change rapidly. The PCL attempted to address this issue by including a more extensive scoring system that would consider assessing how entrenched, chronic, and persistent the traits and behaviors were for each offender across many time points in each offender's life.

Development of the Scale

The PCL was developed using construct validity and statistical analysis. Using Cleckley's clinical construct of psychopathy, Hare and his colleagues listed all the traits, behaviors, and other related features of psychopathy, which resulted in a list of over 100 potential features. Statistical analyses were then conducted using these features to identify redundancy between them, whether they could be scored adequately and reliably, and which ones were effective at discriminating between offenders rated high and those rated low on the global rating scale of psychopathy. These analyses reduced the list to 22 features that were identified to best capture psychopathy and thus formed the structure of the PCL.

Scoring and Administration

The PCL consists of 22 items, each scored on a 3-point ordinal scale (0, 1, or 2). The items represent traits and behaviors that underlie the psychopathy construct. For instance, some items evaluate the emotional processing differences in psychopathy (e.g., lack of remorse or guilt, lack of affect, and emotional depth), and other items assess the behavioral aspects of psychopathy (e.g., short-tempered/poor behavioral controls, many types of offense). Information to score the items is obtained from reviewing the offender's institutional file and conducting a semi-structured interview lasting approximately 1 hour. The PCL was designed for use in criminal populations, and so institutional files are often readily available. The interview portion of the assessment was designed to provide a glimpse of the offender's interpersonal style (e.g., impression management tactics, attitudes) and to elaborate on different areas of the offender's life including education, occupations, family life, marital status, present and past offenses, drug and alcohol use, and health problems. The interview also provides a means to explore the offender's perception and attitudes of his or her offenses and other past behavior. The PCL was designed to incorporate both the interview and file review when assessing for psychopathy.

After reviewing the institutional file and conducting the interview, the items are scored either

a 0 (*definitely not present*) or 2 (*definitely present*) unless there is not enough information or inconsistent information is present to score the item, in which case the item is scored a 1. A completed PCL assessment provides a single total score, which is obtained by summing all the items. This score can range from 0 to 44, where higher scores more closely match the prototypical description of psychopathy. More reliable scores are obtained by taking scores from at least two independent raters and then averaging those scores. The practice of using at least two independent raters also promoted investigations into the interrater reliability of the PCL, demonstrating that its reliability was good, even for non-clinically trained individuals.

PCL Scales

Although the PCL was the original scale developed for the assessment of psychopathy, it was only validated in White incarcerated adult males. Psychopathic traits, though more prevalent in offender populations, are also present in nonoffender adult populations and other populations such as youth. In adult offenders, use of the PCL has been replaced by the updated and revised PCL–Revised (PCL-R) for research and clinical purposes. The PCL-R has retained the structure of the original PCL with some modifications to its scoring and reduction to 20 items.

The PCL has also given form to two other PCL family scales: the PCL: Screening Version (PCL:SV) and PCL: Youth Version (PCL:YV). The PCL:SV is a shorter 12-item rating scale to screen for psychopathic traits and behaviors in offenders and for use in nonoffender populations including forensic psychiatric settings and community samples. The PCL:YV is a 20-item modified version of the PCL-R that is designed for assessing psychopathic traits and behaviors in youth aged 12–18 years. Thus, although not used as a rating scale any longer, the PCL represents the original scale that provided an empirical and conceptual framework for other PCL family scales that are widely used to assess for psychopathy. The development of the PCL and its contribution as the first systematic effort to assess psychopathy in pursuing research underscores its importance and relevance as a research scale.

Use of the PCL in Research and Validation

An initial priority was to validate the PCL as a measure that captured a similar construct as Cleckley's criteria and the global ratings of psychopathy. The first sample to validate the scale consisted of 143 White incarcerated male offenders from a prison in British Columbia, Canada. Analyses showed that PCL total scores significantly predicted global ratings of psychopathy, which indicated that the items that formed the PCL consisted of similar features that clinicians were using when making a clinical decision on the global rating of psychopathy. Another set of analyses found that offenders who were independently scored on Cleckley's criteria and the 22 items of the PCL could be grouped in a similar way, suggesting that both the 22-item PCL and Cleckley's 16 criteria of psychopathy were measuring a similar construct. Early validation analysis, thus, suggested that the PCL was accurately capturing the same or similar construct of psychopathy that clinicians were assessing with global rating scales of psychopathy and Cleckley's criteria, placing confidence in the ability of the PCL to measure psychopathy even without extensive clinical training. Reliability of the scale items and ratings from this initial study also indicated that it could be used confidently as a reliable measure.

As a validated and reliable measure in offender populations, the PCL was subsequently used in research settings to explore the features of psychopathy. One of the first avenues of research examined the relation between the PCL and violence. Some of the early studies reported that offenders with many psychopathic features engaged in frequent and indiscriminate violence. For example, one study found that criminals with higher PCL scores were more likely to commit violent and aggressive criminal acts than those lower in PCL scores. The study also reported that lower IQ was not a reason for this effect. Researchers also examined whether the PCL could predict which offenders would violate the conditions of their community release. Those offenders with high PCL scores received more suspensions and were more likely to commit another crime while on release as compared to those with medium or low PCL scores. Although the PCL was not

designed as a risk assessment measure, there is a substantive amount of research that elevated PCL-R scores are associated with general and violent reoffending. This has made the scale an important part of risk assessment evaluations in correctional settings.

Researchers have also examined the association between the PCL and other mental disorders in forensic psychiatric patients. PCL scores were positively correlated with antisocial, histrionic, and narcissistic personality features and with substance abuse disorders. PCL scores were negatively associated with avoidant personality disorder features. The results of this study led to many other studies examining the overlap between psychopathic traits and other mental disorders.

Other research also found that offenders with high PCL scores were less likely to learn from punishment when there was the prospect of receiving a monetary reward. This finding led researchers to propose that offenders with psychopathic features have a difficult time modulating their responses in the presence of enticing stimuli. These findings laid the groundwork for subsequent research that would corroborate and extend these features and many others into a greater understanding of psychopathy.

Issues and Changes to the Original PCL

The PCL initiated the development of a research scale for the assessment of psychopathy. However, several issues were identified with the scale's validity and reliability. The first issue involved some of the items. The PCL contained 22 items, but 2 items had relatively low correlations with the overall PCL score. These 2 items were Item 2 (previous diagnosis as psychopath [or similar]) and Item 22 (drug or alcohol abuse not direct cause of antisocial behavior). These 2 items were subsequently removed when developing the revised scale, resulting in a total of 20 items (with scores ranging from 0 to 40). In addition, Item 16 (irresponsible behavior as parent) was modified to represent irresponsible behavior across many contexts instead of just parenting.

A second issue was deciding what information about the individual should be used to score each item. Addressing this issue, a more comprehensive guideline and clearer item descriptions were

provided for the revised version of the PCL. This would lead to a clearer expectation of the rater for what information was relevant when scoring each item and would improve the reliability of the scale. A third issue that arose was the consequence of scoring items when little to no information was available for an item. In these circumstances, raters would often lean toward scoring that item a 1 since there may be a chance that the offender shows the features of that item that was not identified from the file review or interview. This approach, however, may have artificially inflated scores since the offender may truly not show the features of that item. To correct this issue, the ability of a rater to omit items and provide prorated scores was suggested and implemented in the revised scale.

Lastly, some of the factors from the factor analysis in the preliminary study did not have underlying content that could meaningfully be communicated. However, refinements of the PCL would later produce the replicable and content-meaningful two-factor structure also found in the PCL-R, PCL:SV, and PCL:YV. This two-factor structure includes a core personality factor (e.g., pathological lying, manipulation, and attenuated emotional features) and an antisocial lifestyle factor (e.g., impulsive, parasitic orientation, and criminal features).

Contribution of the PCL to Understanding and Researching Psychopathy

The primary contribution of the PCL was providing the first assessment scale enabling systematic research into the clinical construct of psychopathy. Before its development, psychopathy was largely a clinical diagnosis, arrived at by interviewing the offender and using clinical judgment to make the diagnosis. The PCL provided a rating scale that combined many of the traits and behaviors of psychopathy using conceptual and statistical methods to provide a more objective assessment of psychopathy.

Another contribution that the PCL provided to research in psychopathy was providing a quantifiable score of psychopathy that could be more easily replicated with various raters. Providing a quantifiable score of psychopathy also enabled research to

examine the dimensional nature of psychopathy and its related features. For example, increasing levels of psychopathy as measured on the PCL indicate an increasing likelihood of violent recidivism. Because the PCL provided a dimensional score (from 0 to 44), research could examine correlations between the PCL and other variables such as recidivism.

Research examining the structure of the PCL also produced a two-factor conceptualization, which has influenced understanding the components of psychopathy. Although the two factors are moderately associated with each other ($r = .50$), they also have distinct properties and associations with the different features of psychopathy. For instance, the antisocial lifestyle factor (i.e., Factor 2) has larger associations with criminal recidivism, drug and alcohol abuse, and psychiatric disorders. The core personality factor (i.e., Factor 1) shows larger associations with instrumental violence and noncompliance with treatment. The two-factor solution first observed in the PCL has also been found in the PCL-R, PCL:SV, and PCL:YV and continues to influence research and understanding of psychopathy.

Another contribution of the PCL was structuring the many features of psychopathy into one scale, where each feature (i.e., item) had the same influence as all the other features (or items) in determining the overall score. Amalgamating the features that form the construct of psychopathy into one scale had the benefit of preventing some salient traits or behaviors from having an undue influence on an offender's score. For example, especially heinous crimes or extensive use of deception may have a dramatic influence when providing a global assessment of psychopathy, but adherence to the PCL scoring would require consideration of the many other features of psychopathy when providing a total psychopathy score. In this way, the PCL provided a balanced, reliable, and accurate way to assess an offender on psychopathic traits for research and clinical purposes and paved the way for not only the PCL family measures of psychopathy but also other assessments that examine the construct of psychopathy and its associated features.

PSYCHOPATHY CHECKLIST–REVISED (PCL-R) AND THE PSYCHOPATHY CHECKLIST SCREENING VERSION (PCL:SV)

Robert Hare's Psychopathy Checklist–Revised (PCL-R) and the briefer screening version (PCL:SV) are the predominant tools for assessing psychopathic traits in adult forensic and correctional

settings. Psychopathy is a multidimensional personality disorder characterized by an arrogant and manipulative interpersonal style, poverty in major affective reactions, an impulsive and irresponsible lifestyle, and persistent and inadequately motivated antisocial behavior. Contemporary conceptualizations of psychopathy derive from Hervey Cleckley's seminal work in the 1940s in which he provided comprehensive descriptions of institutionalized psychiatric case studies. Cleckley defined psychopathy primarily in terms of interpersonal and affective deficits under a surface of outwardly *normal* behavior, which he termed a *mask of sanity*. Considerable research has demonstrated that adults presenting with psychopathic traits embark on a chronic, proactively (i.e., without provocation, for instrumental gain) aggressive, violent, and criminal lifestyle, and as such are highly overrepresented in the criminal justice system.

The PCL and its derivatives are often used by clinicians and forensic professionals for violence risk assessment, although not originally intended for this purpose. In fact, in his case descriptions, Cleckley did not characterize psychopaths as explosively violent, predatory, or cruel; rather, he suggested that the harm that they caused was secondary to their shallow affect. Modern perception of psychopathy's association with criminal antisocial behavior stems from William and Joan McCord's work with incarcerated offenders, rather than psychiatric patients. Many current measures of psychopathy assess law-breaking behaviors in addition to the core affective and interpersonal features, which some scholars view as tangential to the construct, constituting a matter of contention. This is due in part to the fact that most existing measures of psychopathy are based on the PCL, which weighs antisocial and criminal externalizing features as strongly as the traits of emotional detachment and interpersonal exploitation. Research finds that the predictive utility of PCL assessments is largely derived from its assessment of antisocial and disinhibitory tendencies rather than interpersonal and affective features.

Psychometric Properties and Factor Structure

Hare's initial efforts toward developing this clinical diagnostic instrument consisted of a global

ratings system that was based on Cleckley's institutional description, in which a diagnostic rating from 1 to 7 was assigned to indicate an individual's likeness to a prototypical psychopath (1 = *clearly nonpsychopathic*, 7 = *definitely psychopathic*). However, this original rating system required considerable experience and knowledge of Cleckley's conceptualization and was not easy to disseminate to other researchers or clinicians. Hare's original checklist consisted of 22 items that were chosen from a larger item pool on the basis of how effectively they discriminated, as a set, between high and low scores on the global ratings system. Individuals' likeness to a prototypical psychopath was rated on a 3-point scale (0 = *item does not apply*; 1 = *item applies somewhat*; 2 = *item definitely applies*). The subsequent revised version (PCL-R) dropped two items ("previous diagnosis of psychopathy or similar" and "antisocial behavior not due to alcohol intoxication") from the original checklist with poor factor loadings and included clarified scoring criteria for ease of use for evaluators.

PCL assessments are to be conducted by trained professionals with semi-standardized administration procedures. The PCL-R involves a 60- to 90-minute semi-structured clinical interview supplemented with an extensive case history institutional file review, providing a fairly objective assessment of adult psychopathy. The individual is rated on 20 psychopathic traits that define psychopathy across two dimensions: an interpersonal-affective dimension (Factor 1; divisible into affective and interpersonal facets) and a lifestyle-behavioral dimension (Factor 2; divisible into impulsive-irresponsible lifestyle and antisocial behavior facets). PCL manuals provide a description of each item and information to be used in decision-making when rating an individual. The standard interview covers a range of topics including education, employment history, family and home life background, relationships and children, drug and alcohol use, and criminal history. Item ratings are summed to yield a global score representing the degree to which the individual embodies the prototypical psychopath with a maximum score of 40. Individuals scoring equal or greater than 30 have traditionally been designated as psychopathic and at high risk of violent, antisocial behavior.

The PCL:SV was developed as a briefer version of the PCL-R to screen for psychopathy and to determine whether more comprehensive assessment is warranted. This abbreviated version includes 12 items that are thought to be representative of Factor 1 and Factor 2 from the PCL-R (labeled Part 1 and Part 2) and has been used with civil psychiatric patients, community samples, and in personnel selection. Items removed include pathological lying, shallow affect, need for stimulation, parasitic lifestyle, promiscuous sexual behavior, many short marital relationships, early behavior problems, and criminal versatility. PCL:SV scores correlate strongly with the PCL-R (weighted $r \sim 0.80$). Similar to the PCL-R, each item is rated on a 3-point Likert-type scale by trained professionals based on a clinical interview and file review. While factor analyses were not completed in the original development of the PCL:SV, some factor analytic studies conducted since support the same two-factor structure as the PCL-R. Others have found support for a three-factor model across PCL measures tapping moderately correlated ($r \sim 0.50$) but separable affective (e.g., callousness/lack of empathy), interpersonal (e.g., glibness and superficial charm), and antisocial-behavioral deviance (e.g., chronic impulsive and irresponsible behavior, life-span antisocial behavior) dimensions.

Convergent and Discriminant Validity

PCL scores correlate more strongly with the McCord's definition of criminal psychopathy rather than Cleckley's masked disturbance of attenuated affect. High PCL-R and PCL:SV scores are positively associated with measures of impulsivity, aggression, and criminal behavior (i.e., convergent validity—measures that should be related are related) and inversely associated with measures of empathy and affiliation (i.e., discriminant validity—measures that should not be related are not related). Specifically, research indicates that high scores on the interpersonal-affective dimension are associated with narcissism, social dominance and potency, and low empathy and negatively related to measures of negative emotionality (i.e., anxiety and depression). Those scoring high on the interpersonal-affective dimension also show reduced fear-potentiated startle in the

presence of threat. Conversely, the lifestyle-behavioral factor is associated with alienation and externalizing maladaptive characteristics and behaviors, such as aggression, impulsivity, sensation seeking, drug and alcohol use, and criminal behavior.

Predictive Validity

PCL measures were not developed for the explicit purpose of risk assessment, for which many validated tools are available; however, they show clinical utility for predicting nonviolent and violent criminal recidivisms. As a consequence, they have increasingly been used in a variety of legal contexts, both criminal and civil, to assist risk assessment in cases regarding commitment pursuant to sexual predator laws, civil commitment, parole determinations, institutional placement, death penalty sentencing, and sentence enhancement/mitigation. Surveys of U.S. forensic practitioners suggest that the PCL-R, specifically, is among the most commonly used clinical instruments for assessing recidivism risk.

Meta-analytic studies examining whether PCL measures can predict recidivism consistently reveal a small to moderate association between PCL total scores and future offending, including institutional behavior problems and general and violent recidivism. This finding is observed among male and female offenders, juvenile offenders, forensic psychiatric inpatients, community samples, and European samples. Research examining the PCL's predictive validity has predominantly been conducted with White North American male samples; however, recent efforts have attempted to validate its use with other ethnicities, but further research is needed to determine the reliability of the measure with these samples. The predictive validity of PCL scores is generally stronger when longer follow-up intervals are used. The PCL does exhibit adequate predictive validity for general and violent recidivism among sexual offenders but is less useful in the prediction of sexual reoffending specifically. Thus, it is clear that the PCL measures demonstrate at least some degree of predictive validity with regard to future antisocial behavior.

As mentioned earlier, most of the PCL's predictive utility is attributable to its assessment of

antisocial deviance features of psychopathy rather than interpersonal traits reflecting emotional detachment. Several meta-analyses consistently demonstrate that the lifestyle and antisocial-behavioral features of the PCL, which assesses general externalizing psychopathology that is not specific to psychopathy, more strongly predict future antisocial conduct than the interpersonal and affective features. The relative superiority of the lifestyle-behavioral deviance dimension for predicting antisocial behavior holds true across various outcome measures, including institutional misconduct and general and violent recidivism. These findings challenge the assumption that the measures' association with violence is an indication that emotionally detached psychopaths use violence to prey upon others. However, some research has demonstrated that Factor 1 is more strongly associated with instrumental aggression relative to Factor 2 that is more strongly associated with reactive aggression. The PCL measures may tap trait aggression, externalizing features, or a chronic and versatile history of antisocial behavior that predicts future violence but are not specific to psychopathy. It has been further suggested that psychopathy dimensions may have an additive or interactive effect such that the prediction of recidivism or violence is substantially enhanced when they are considered together, although findings are inconsistent.

Recommendations for Use

The popularity of PCL measures in forensic risk assessment appears to transcend tools developed specifically for the purpose of evaluating risk of future offending; however, some important considerations are worth mentioning. First, Hare recommended that PCL measures are not appropriate for use as a stand-alone risk assessment tool. Rather, PCL measures may be best utilized as a complement to other risk assessment tools that have been designed to predict specific outcomes. Second, while both the PCL-R and the PCL:SV have recommended cutoff scores (>30 and >18 , respectively) constituting a psychopathy *diagnosis*, this is founded on little research support. There is still surmountable debate in the field on an accurate psychopathy definition; however, researchers support that psychopathic traits are

continuous (i.e., dimensional) rather than taxonic (i.e., categorical). Third, in the tool's development, Hare excluded Cleckley's positive adjustment indicators regarding these items as irrelevant to the psychopathy construct. Other researchers have disagreed with this exclusion, suggesting that characteristics of fearlessness and stress immunity are essential elements of psychopathy. Cleckley described individuals with such paradoxical positive adjustment and maladaptive features, a combination of traits often observed among individuals in certain professions, such as, politicians or investment bankers—a subgroup some in the field have termed *successful* psychopaths. In contrast, some individuals designated as psychopathic according to the PCL and its derivatives present with high anxiety levels or other emotional maladjustment and are typically described as secondary psychopathy variants in the literature.

Although phenotypically indistinguishable from primary psychopathy variants with regard to both Factor 1 and Factor 2 traits, experiences of social and environmental adversity (i.e., childhood trauma or maltreatment) are instead central to theories of secondary psychopathy. Several studies have also found that secondary psychopathy variants show a more reactively aggressive and violent profile than primary variants. Since “an absence of anxiety or other ‘neurotic’ symptoms” was dropped as an indicator between Cleckley's psychopathy criteria and PCL assessments, some researchers include measures of negative emotionality (i.e., anxiety) to distinguish secondary psychopathy variants.

Finally, several researchers and clinicians believe that psychopathic individuals are resistant to treatment, and consequently, PCL assessments have been used to exclude those scoring in the psychopathic range from receiving treatment. However, accumulating research by Stephen Wong and colleagues finds that psychopathic offenders receiving comprehensive and intensive intervention focused on targeting criminogenic behaviors and individual interpersonal personality features, in line with the Risk-Need-Responsivity principles, commit less serious offenses than matched controls receiving standard correctional programs. Also, in light of the aforementioned research supporting heterogeneity among those with psychopathic traits, a one-size-fits-all approach to intervention may not be

capturing the unique treatment needs of psychopathy variants that show distinct correlates and putative etiological factors.

In conclusion, there is still disagreement in the field as to how best to operationalize the prototypical psychopath. However, with the development of the well-validated PCL assessment and its derivatives, including a youth version, scientific research on psychopathic traits is abundant. The PCL was not designed to be used as a risk assessment tool; however, it is commonly used in judicial settings to identify those individuals at greatest risk of persistent, violent, antisocial behavior. In the United States, specifically, the use of PCL measures in the courtroom is increasingly introduced by prosecution in capital punishment cases and as a determinant in treatment allocation. Yet, research has found that adult psychiatric patients scoring high on the PCL-R and receiving targeted, intensive intervention were less likely to behave violently and committed less serious offenses than those who attended fewer treatment sessions or received standard treatment. Continued research efforts to elucidate how the various dimensions of psychopathy, alone and in combination with anxiety measures, designate a subgroup of antisocial individuals at greatest risk of persistent violence and lawbreaking behavior hold promise toward informing theory and practice.

PSYCHOPATHY CHECKLIST: YOUTH VERSION (PCL:YV)

The PCL:YV is an assessment that measures psychopathic traits and behaviors in youth aged 12–18 years. The construct of psychopathy has been studied in adults with structured assessment measures developed by Robert Hare since the 1970s using the Psychopathy Checklist (PCL), which later became the PCL-Revised (PCL-R), a measure of psychopathy widely used in research, clinical, and forensic settings. The PCL:YV was adapted from the PCL-R and published in 2003. It has the shared goal among researchers and clinicians of identifying psychopathic traits and their consequences in youth, with the potential to shed light on the developmental precursors of adult psychopathy. Furthermore, it provides a means to discover the persistence of these traits from adolescence to adulthood and to assess the effectiveness of early intervention. Adult psychopathy is related to many negative social and individual outcomes, including violent reoffending, instrumental aggression, substance abuse, and treatment dropout. The PCL:YV was constructed to learn the developmental history of psychopathy and its early manifestation with the goal of ameliorating these negative outcomes. This entry describes the structure and administration of the PCL:YV, special considerations when assessing adolescents, its psychometric properties, and its application for understanding the construct of psychopathy in youth.

Structure and Administration

The PCL:YV is a 20-item rating scale completed on the basis of a semi-structured interview and a collateral file review. The rater scores each item on a 3-point scale from 0 to 2, where 2 is *definitely present*, 1 is *somewhat present*, and 0 is *not present*, resulting in a total score ranging from 0 to 40, with higher scores representing more psychopathic traits and behaviors. The file review is typically conducted first to gather and organize information and to help prepare questions for the interview. A rater who typically has an advanced professional or university degree (e.g., MD, MA, PhD) conducts the interview with the youth, which takes approximately 120 minutes. The interview probes different aspects of the youth's life, including the youth's history and current functioning, school, work, family background, relationships, substance use, attitudes, emotions, and antisocial behaviors. As a semi-structured interview, its trajectory may change depending on the flow of conversation, cooperation, and types of information shared by the youth. Although not preferable, when an interview is not possible (e.g., youth or parents withhold consent), a PCL:YV assessment can still be conducted with just a file review. File review-only assessments, however, should contain multiple sources of information from varied contexts, should be noted in the assessment report, and its results interpreted cautiously.

The PCL:YV manual provides a detailed description of each item for assessors to minimize rater differences when scoring. In addition to detailed descriptions of each item, the manual provides information on where to find the source of information. These are details and illustrations that give the assessor an indication of what information during the interview and/or file review is relevant and helpful for scoring each item.

PCL:YV items can be grouped according to factor analysis into four clusters of traits and behaviors. Four items comprise an *interpersonal* traits factor, which include items such as manipulation and impression management. Four items make up an *affective* traits factor, including items such as lack of remorse or guilt and callousness/lack of empathy. Five items form the *behavioral* traits factor, including irresponsibility and impulsivity, among others. Five items also comprise an

antisocial traits factor, with items such as criminal versatility and poor anger control. The two additional items are stand-alone items that do not load onto one of the four factors. Item scores are summed to produce a PCL:YV total score, with higher scores indicating more psychopathic traits and behaviors.

Considerations for Measuring Psychopathy in Youth

Any measurement of young individuals needs to take into consideration that youth are developmentally unique compared to adults. The PCL:YV incorporated the following age-related considerations into its development.

Nonnormative Behavior

Assessing with the PCL:YV requires a consideration that the degree of normal or average behavior in adolescence is different from that in adults. For instance, risk-taking behavior is more common in youth compared to adults. Therefore, scores on the PCL:YV items must reflect levels of traits and behaviors that are nonnormative for youth.

Age-Appropriate Items

Items should be considered in light of the different expectations, responsibilities, and developmental stages of youth compared to adults. For example, most youth in modern society are not expected to have an extensive work history or have dependents, and they typically have different psychological and emotional concerns compared to adults. Based on this criterion, assessors are expected to be familiar with what is normal adolescent development.

Stable Characteristics

When assessing youth with the PCL:YV, it is essential to consider a range of ages from childhood to the time of the assessment when scoring items. This will prevent the undue influence of any transitory problems in a youth's life on the youth's score. For example, an adolescent whose parents have recently divorced may be acting more antisocially since the divorce. It is also important to

consider many contexts (e.g., school, home, community) over the youth's lifetime when assessing stability of a characteristic.

Multiple Sources

The file review must contain multiple sources of information about the youth to avoid undue influence of one or a few perspectives that may have limited social interaction with the youth. Having many sources allows for a comparison between observers of the youth and the youth's perspective during the interview. Sources may include parent and teacher reports, mental health records, and criminal and court records.

Labeling

As an offender in the criminal justice system, the label *psychopath* can have negative consequences on severity of sentencing, probability of parole, and access to institutional programming and treatment. Therefore, the PCL:YV developers stress that anyone using the PCL:YV must not interpret any score as evidence that the youth is a *psychopath*. Furthermore, they stress that the PCL:YV should not be the sole assessment used in clinical and forensic decision-making.

Psychometric Properties

Overall, the PCL:YV demonstrates strong psychometric properties. The interrater reliability of PCL:YV Total scores is high within research settings (single-rater intraclass correlation coefficients of .90–.96). However, it is not clear if the same interrater reliability is evident within real-world contexts. The internal consistency of PCL:YV Total scores is also high, with α coefficients ranging from .85 to .94. The factor scores have more variable reliabilities, with interrater reliability ranging from acceptable to excellent (.70–.90) and internal consistency ranging from questionable to excellent (.22–.86).

Research has been conducted with institutionalized young offenders, young offenders on probation, psychiatric inpatient youth, and youth in the community. PCL:YV Total scores do not appear to be unduly influenced by youths' age, gender, or ethnicity. The PCL:YV is standardized on these

samples, with 2,438 youth from Canada, the United States, and the United Kingdom. After a PCL:YV assessment, the youth's score (Total and/or Factor) is compared to percentile and *T*-score tables, which compare the relative level of psychopathic traits of that individual to other youth in similar circumstances (institutionalized, probation, or community) and of the same gender. For example, youth scoring in the 90th percentile will have 90% of youth from the same circumstance and gender score less than them on the PCL:YV. This indicates a high level of psychopathic traits for that youth.

Applications and Uses

The PCL:YV is used in various research, clinical, and forensic settings to help determine the presence of psychopathic traits in youth, including the differences and similarities between youth and adult psychopathy and between youth with high compared to low psychopathic traits. Much of this research has confirmed the validity and utility of the PCL:YV as a measure that is similar to psychopathy in adults as assessed with the PCL-R.

The PCL:YV has been used to determine whether higher psychopathic traits exist more in adolescents who have experienced adverse childhood environments. Higher PCL:YV scores have been associated with separation from mothers or fathers at earlier ages, maternal criminality and number of nonviolent offenses, and lack of parental supervision. There has been no established relationship, however, between PCL:YV and parental substance abuse or whether the youth was adopted. Some researchers have found no relationship between higher PCL:YV scores and parental abuse generally, but others have reported a relationship between higher PCL:YV scores and physical abuse from the father specifically.

Another important use of the PCL:YV is to better understand developmental differences in social, neurocognitive, and intelligence traits of youth who are high compared to low in psychopathy. Higher PCL:YV scores are associated with a diminished empathic response and moral reasoning capabilities on neurocognitive tests. Higher scores are also associated with making more errors on a go/no-go task that is mediated by the orbitofrontal/ventromedial areas of the brain but

not with errors on tasks mediated by the frontal/dorsolateral areas of the brain. In addition, some evidence has shown that the volume of some brain areas is identifiably different based on PCL:YV Factor scores. Intelligence appears to manifest differently in youth scoring higher on the first factor of the PCL:YV (interpersonal traits) compared to youth with lower scores. Youth with higher PCL:YV interpersonal traits may have higher verbal IQ and show more creativity, practicality, and analytic thinking based on standardized measures. PCL:YV Total scores have been positively associated with performance IQ in some studies, but others have shown that youth scoring high on the PCL:YV have comparable IQ scores to those scoring low. Researchers and clinicians often consider these strengths and weaknesses when formulating intervention programs to promote effective change.

The PCL:YV is related to antisocial behavior in youth. There is a higher preponderance for violent antisocial behavior in both institutions and the community for youth with high PCL:YV scores. Youth in correctional institutions with high PCL:YV scores have more infractions and show more physical violence compared to those with lower scores. Other antisocial indications that distinguish high PCL:YV youth from low PCL:YV youth are a greater presence of instrumental motives for violence (using aggression toward others to get something) and victim injury (the severity and type of injury the victim sustained). Along with preponderance for antisocial behavior, those with higher PCL:YV scores also have an earlier onset of criminal activity, higher frequency of criminal activity, and more versatility in the types of crimes they engage in, even after removing the items within the PCL:YV, which are used to score criminal behavior. These patterns have also been found in some ethnic minorities assessed with the PCL:YV.

There is a well-established positive relationship between PCL:YV scores and violent reoffending, but this relationship has largely been found only with boys. A mean 10-year follow-up study into young adulthood of young offenders assessed with the PCL:YV found that it was a strong predictor of violent, nonviolent, and sexual reoffending, with approximately half the youth later receiving an adult conviction. The relationship between the

PCL:YV and sexual reoffending, however, is not well established. Although youth with elevated PCL:YV scores are more likely to reoffend, some researchers have demonstrated that an intensive treatment program for such youth has been successful at reducing violent reoffending rates compared to conventional detainment.

The PCL:YV has extensive research that has investigated psychopathic traits in youth and found that many similarities exist with research from the adult psychopathy literature. This supports the use of the PCL:YV as a valid measure of a similar construct of psychopathy as measured by the PCL-R for adults. There has not been, however, longitudinal studies investigating the concordance between PCL:YV scores and PCL-R scores in the same individual. Furthermore, despite there being a relationship, not all youth scoring high on the PCL:YV go on to have criminal involvement. There may, therefore, be mediating factors that contribute to the traits assessed with the PCL:YV and its association with future criminal behavior. Discovering these mediating factors is the goal of researchers and clinicians to assist with identifying potential variables that might be considered when implementing more effective interventions for youth with high psychopathic traits.

PSYCHOPATHY VERSUS ANTISOCIAL PERSONALITY DISORDER

Psychopathy is often considered a severe personality disorder, and perhaps more accurately, a constellation of several maladaptive personality traits. More specifically, those who traditionally are viewed as *psychopaths* tend to be regarded as superficially charming, manipulative, pathological liars, egocentric, overly self-assured, callous, exploitative, insensitive, having shallow or no emotions, lacking in guilt and remorse for their actions, as well as being impulsive, irresponsible, and aggressive. Psychopathy expert Robert Hare has referred to them as *intraspecies predators* who, via the use of charm, manipulation, and intimidation, callously take what they want, and abuse or exploit whoever stands in their way to achieve their goals, without the slightest sense of regret or remorse.

While such psychopathic individuals are relatively rare, when one does encounter such a person, the effects usually include being victimized emotionally, sexually, and financially within the context of what may have begun as an intimate or friendly relationship. Furthermore, these individuals are responsible not only for a disproportionate amount of antisocial conduct in society, especially violent and sexual crime, but also for malfeasance in the workplace and other settings. A great deal of research has shown that criminals who have been assessed as being psychopathic are more likely to commit new crimes, including violent crimes such as sexual assault, than nonpsychopathic offenders. As such, psychopathy has become a very important construct in criminal and forensic psychology.

Interestingly, psychopathy per se is not listed as a diagnostic entity in the current version of the

Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5), published by the American Psychiatric Association in 2013. The DSM-5 does, however, provide a diagnosis of a personality disorder that includes many of the criteria of psychopathy as described earlier, namely, antisocial personality disorder (APD), and notes that terms such as *psychopathy*, *sociopathy*, and *dissocial personality disorder* have been used to indicate APD. The following paragraphs provide for a historical and contemporary account of the diagnosis of psychopathy and discuss the adequacy of the current diagnostic operationalization of this psychological construct.

Diagnosis of Psychopathy

Historical Accounts and Contemporary Conceptualizations

Psychopathy, as it is currently conceived, can be traced back to the 19th century. As early as 1801, the father of modern psychiatry, Philippe Pinel, wrote about a condition he labeled *manie sans delire*, which translates to “mania without delirium.” Individuals with this condition showed extreme behavioral dysfunction, including cruelty, exploitation, aggression, and impulsivity but otherwise appeared to be of rational mind. In 1835, James Pritchard, perhaps the first scholar to use the term *mental disorder*, described a group of patients as being morally deficient but having otherwise unremarkable intellect or ability to reason. Later in 1904, Richard von Krafft-Ebing, a psychiatrist who specialized in criminal behavior, and sexual deviance in particular, characterized these individuals as morally depraved and societal savages who were primarily motivated by needs for aggression and exploitation. In 1915, Emil Kraepelin, the father of contemporary descriptive nosology who wrote the precursor to the *DSM*, referred to a certain group of antisocial patients as *swindlers*—those who were born criminals and the most vicious of all offenders.

Hervey Cleckley, an American psychiatrist, is often referred to as the first scholar to provide the contemporary account of psychopathy. In his classic 1941 book, *The Mask of Sanity*, he described 15 case studies of patients who were quite different from the other patients in the hospital in

which he worked. Much like Pinel's early accounts, these patients were socially adept, manipulative, deceitful, self-centered, and generally guiltless/remorseless and engaged in impulsive and irresponsible behavior. However, they appeared generally free of the debilitating mental health problems (e.g., depression, anxiety, psychosis, suicidality) that characterized the other patients; hence the *mask* or appearance of psychiatric well-being in the light of their highly maladaptive and socially impaired conduct.

Cleckley's original account inspired many other scholars, and some accounts of the nature of psychopathy have varied since that time. In 1964, William McCord and Joan McCord wrote *Psychopathy: An Essay on the Criminal Mind*, which detailed their studies of psychopathy among prison inmates. Their account of the psychopathic personality generally converged with that of Cleckley's on many points, but their description diverged on the motivational aspects of the disorder. McCord and McCord argued that psychopathic individuals were emotionally cold, socially detached, dangerous/aggressive, and motivated by rage rather than fear or anxiety. In essence, they were cold, vicious, and predatory.

Hare, a Canadian psychologist often credited with being the most prolific writer on the subject of psychopathy, developed the Psychopathy Checklist in an effort to unify the operationalization of this construct, although it was largely based on Cleckley's model of psychopathy with some modifications. The revised version, Psychopathy Checklist-Revised (PCL-R), which was published in 1991, was made available for psychological practice and has been cast as the only method to *diagnose* psychopathy. The use of (PCL-R) involves conducting a semi-structured interview with the client that, combined with a thorough review of the individual's institutional (e.g., prison, hospital) records, allows a clinical psychologist (or similarly trained mental health professional) to rate a person on 20 specific traits/behaviors (e.g., superficial charm, grandiose sense of self, cunning and manipulative, lack of remorse, callous/lack of empathy, impulsivity, irresponsibility, criminal versatility) that are definitional of psychopathy. It is important to note, however, that the PCL-R is just one of many instruments that measure the psychopathic personality. There is nothing

inherently diagnostic about the tool, but offenders who score above a prescribed cutoff have been found to be at a much higher risk of recidivistic antisocial behavior.

Formal Diagnostic Operationalization

As mentioned earlier, the only formal diagnosis that is meant to target *psychopathic personality disorder* in the *DSM-5* is APD. Some experts on the topic have argued that this is an inadequate diagnostic operationalization of psychopathy, and others have argued that psychopathy and APD are different disorders. However, when examining the evolution of the APD construct throughout the various versions of the *DSM*, it becomes evident that APD has been intended to capture the psychopathic personality.

DSM-I, which was published in 1952, referenced an *antisocial reaction* type of sociopathic personality disturbance, entailing not only a deviation from traditional societal values and norms, but features including failure to learn from experience, disloyalty, callousness, excitement seeking, showing marked emotional immaturity, and a lack of sense of responsibility. The *DSM-I* even noted that individuals assigned this diagnosis would have previously been described as exhibiting a psychopathic personality. *DSM-II*, which was published in 1968, settled on the term *antisocial personality*, but the description was again in line with earlier conceptions of psychopathy, describing individuals with this disorder as self-centered, callous, irresponsible, lacking in guilt/remorse, and failure to learn from punishment and other experiences. Moreover, *DSM-II* noted that merely possessing an extensive history of criminal conduct was insufficient to warrant the diagnosis. Whereas these two early definitions of antisocial personality were closer to Cleckley's and McCord and McCord's classic descriptions of psychopathy than more recent versions of the *DSM*, they lacked sufficient diagnostic reliability, due to their reliance on prototype matching rather than on explicit diagnostic criteria.

Owing to the goal of increasing diagnostic reliability in *DSM-III* (published in 1980) through the use of explicit descriptive criteria, APD was operationalized through various behavioral criteria representative of irresponsibility, aggression, unlawful

behavior, recklessness, and impulsivity. Some of the changes in *DSM-III* APD reflected the work of Lee Robbins, who noted that traits were more inferential and subjective, whereas behaviors were more reliable. Moreover, the presence of conduct problems prior to age 15 years was included to indicate the permanency of the behavioral disturbance. Published in 1987, a revised version of the *DSM-III* maintained the behavioral criteria from *DSM-III* but added an additional criterion of lacking in remorse for one's behavior. The *DSM-IV* and *DSM-IV, Text Revision*, published in 1994 and 2000, respectively, operationalized APD in a manner similar to that of its revised version of the *DSM-III* counterpart in its coverage of various social deviance behaviors. Although the text in the manual noted that the diagnosis of APD was synonymous with psychopathy by describing its associated features as glib, superficially charming, callous, and lacking in empathy (among others), none of these features were included in the actual diagnostic criteria. Finally, the *DSM-5* retained the text from *DSM-IV, Text Revision*, almost verbatim.

Convergence and Divergence Among Operationalizations

It is important to note that the *DSM* and instruments such as the PCL-R are merely operationalizations, or measurements, of a theoretical construct, here, psychopathy. Such operationalizations are very much dependent on theory, which in the field of psychopathy continues to be somewhat controversial. The most common perspective in the field is the one held by Hare (which was heavily influenced by Cleckley as noted earlier but likely came to resemble that of the McCords' to a greater degree) which guided his development of the PCL-R. The *DSM-5* operationalization of APD and the PCL-R operationalization of psychopathy have several similarities: Both emphasize interpersonal deceitfulness, lack of remorse, impulsivity, irresponsibility, aggressiveness, and general social deviance throughout the life span. The PCL-R also contains the assessment of superficial charm, grandiose sense of self, callousness/lack of empathy, lacking in emotional depth, failure to accept responsibility, and need for stimulation/excitement. Many of these latter characteristics tend to be common across many theoretical formulations of

psychopathy, making the *DSM-5* operationalization incomplete or inadequate. Furthermore, only three of seven criteria (along with evidence for conduct problems prior to age 15 years) are necessary for a diagnosis of APD; as such, many so-called career criminals who are impulsive and irresponsible would meet criteria for APD, which appears to be inadequate in light of theoretical formulations that emphasize the specificity of the more emotional (e.g., lack of empathy, remorse, and emotional depth) and interpersonal (pathological lying, superficial charm) characteristics and central to the disorder.

This very broad and heterogeneous APD operationalization typically means that 50–75% of prison inmates meet diagnostic criteria for the disorder, which may not be particularly useful for offender management, including risk classification and intervention. It is not surprising that most individuals who meet the criteria for psychopathy (per the PCL-R) also meet most of the criteria for APD (including those of conduct disorder before age 15 years) plus many of the additional features unique to psychopathy. However, given that the percentage of prison inmates who meet the criteria for psychopathy is more restricted (only 15–20% of those who meet the criteria for APD), a finding of psychopathy may be more informative in terms of offender management than a *DSM-5* diagnosis of APD.

A Look to the Future

Prior to the *DSM-5* publication in 2013, a working group on personality and personality disorders had proposed revising the personality disorder section of the *DSM* (to which APD belongs) and substituting it with a model that emphasized the individual differences that personality traits coupled with dysfunction. The proposed model was eventually placed in Section III (Emerging Models and Measures) of *DSM-5* for further scientific examination. Because the list of traits considered for *DSM-5* Section III APD include callousness, manipulateness, deceitfulness, hostility, impulsivity, irresponsibility, and risk-taking, it seems apparent that the Hare psychopath is approaching diagnostic reality. Also proposed was a *psychopathy specifier* that captures the low anxiety and social gregariousness typically attributed to the theoretical construct of psychopathy. Initial

scientific research indicates some validity to this alternative operationalization; however, more scientific work is needed. Nevertheless, the *DSM* appears to be moving toward mapping its operationalization of psychopathy onto the theories from which it was originally derived.

PUBLIC OFFENDER REGISTRIES

The registration of criminal offenders in the United States is not a new approach to crime prevention, but since the 1990s, this effort to create and maintain systematic lists of lawbreakers has focused largely on convicted sex offenders and featured public offender registries (PORs). As repositories of information about convicted criminals, PORs are open to anyone who wishes to access such data and are often made available through the online web pages of government entities and other organizations. Upon criminal conviction, individuals subjected to PORs are typically required to provide law enforcement and correctional authorities with their names, photographs, addresses, birth dates, Social Security numbers, fingerprints, offense histories, and dates of convictions. However, the information provided to the public varies widely across jurisdictions. These offenders must also verify the accuracy of this information on a routine basis for the duration of their registration, which may range from a few years to the rest of their lives. This entry describes

the rationale behind PORs and early attempts at criminal registration in the United States. PORs are then considered in light of their effects on public safety and recidivism, ramifications for offenders and families, and other criticisms. Finally, the newest developments in PORs are discussed.

Rationale Behind PORs

The expressed goals of PORs are to promote public safety and reduce recidivism through deterrence. Proponents assert that PORs allow the public to recognize convicted offenders who may continue to pose a threat to communities. The idea is that PORs may prevent crimes by identifying people with proclivities toward offending (due to their criminal records) and allowing society to respond accordingly. Responses may include protective actions by citizens or barring identified offenders from employment, housing, community engagement, and other forms of social capital that may place other community members at risk of victimization. Thus, PORs allegedly increase awareness of potential danger and allow community members to be better prepared to avoid situations in which identified offenders living among them may reoffend. At the same time, the possibilities for participating in criminal activities again are believed to be restricted, as public identification and exposure of previous crimes supposedly make offenders feel more susceptible to the risks associated with repeating offenses.

Early Criminal Registration

Concerns about organized crime in the 1930s led to the establishment of the earliest criminal offender registries in the United States. In 1933, Los Angeles, CA, passed the first ordinance that mandated registration of individuals who were convicted of certain crimes. The goals of this law were to send a message to *gangsters* and other lawbreakers that the city was not a desirable place to conduct illegal activities and to provide the police with the ability to track convicted offenders to reduce recidivism. Shortly thereafter, criminal registries became realities in many U.S. jurisdictions, such as Miami, FL, and Seattle, WA, but these laws were anything but uniform. The types of offenders subjected to registration, the

information that was maintained, and penalties for failing to register differed. Florida, in 1937, was the first to successfully pass statewide legislation that obligated certain individuals to register as convicted criminals.

In the succeeding decades, several other states created and enforced criminal registration statutes. California implemented such registration in the late 1940s, whereas Arizona, Illinois, and New Jersey did so in the 1950s. Alabama, Nevada, and Ohio followed suit in the 1960s. The laws in California, Arizona, Alabama, Nevada, and Ohio focused solely on convicted sex offenders, and the laws in Illinois and New Jersey were aimed only at drug offenders. In the 1980s, however, Arkansas, Montana, Oklahoma, and Utah established registration procedures for convicted criminals, and these policies often centered on all felons, individuals who engaged in offenses against morality, or both. Although they were popular among lawmakers, early criminal registration efforts were largely undermined and often unenforced by the police and prosecutors who acknowledged their expensive nature, implementation challenges, and lack of effectiveness for stopping crime.

Creation of PORs

It was not until the high-profile sexual attacks on children and moral panic over sex offenders in the 1990s that U.S. criminal registration schemes allowed the public to access information about convicted offenders. The Jacob Wetterling Crimes Against Children and Sexually Violent Offender Registration Act (1994) was the first federal law that mandated registration of sex offenders in statewide databases. As a result of the Wetterling Act and subsequent legislation, each state now has a mandatory registration law that obligates sex offenders to provide their information to law enforcement officials and have this information provided to the public, most often through publicly available Internet registries. However, it was Megan's Law (1996) in New Jersey that created sex offender registration and notification (SORN) legislation that was ultimately replicated nationwide. Responsible for transforming sex offender registries into publicly available online domains, the federal version of this statute (Public Law 104-145) requires state police agencies to make

information about sex offenders accessible to the public. The Adam Walsh Child Protection and Safety Act became law in 2006 and created a comprehensive and national system for sex offender registration.

Effects on Public Safety and Recidivism

Because PORs have historically targeted convicted sex offenders, what is known in the research literature about their utility is limited to SORN. Nonetheless, it appears that PORs do not increase public safety or decrease recidivism. There is an assumption that PORs increase awareness of the presence of convicted offenders in communities. However, a large majority of the public does not actively utilize available information that is disseminated through online sex offender registries. Although residents commonly know that sex offender registries exist, they often do not use them. This may subsequently reduce community members' awareness of such offenders. Indeed, most residents are ignorant of the presence of sex offenders in their communities, even when they access sex offender registries or live directly adjacent to registered sex offenders. Thus, while community members are largely aware of publicly accessible sex offender registries, such mechanisms do not appear to raise actual public awareness of the presence of local sex offenders. When the public does utilize sex offender registries to become informed about convicted sex offenders in their neighborhoods, this strategy often leads to excessive precautionary behavior and fear of crime that may be harmful.

Placement on PORs generally does not influence the behavior of individuals who are listed on such databases. Whether or not convicted sex offenders were subjected to SORN failed to predict which sex offenders would sexually recidivate in Arkansas, Iowa, Massachusetts, New Jersey, New York, and Washington. This indicates that publicly identifying convicted offenders does not effectively deter them from repeating crimes. What is more, there is some evidence that SORN increased recidivism rates among convicted sex offenders. In short, research on convicted sex offenders across two decades and several U.S. jurisdictions indicates that PORs fail to improve public safety.

Ramifications for Offenders and Their Families

Once individuals are listed on PORs, they often report negative experiences that stem from their public exposure. As the targets of SORN laws, sex offenders often directly encounter harmful obstacles that prevent them from easily reintegrating into society after sex offense convictions. These collateral consequences are the unfavorable and often unintended outcomes that may exist in association with criminal penalties. Convicted sex offenders who are placed on PORs commonly encounter numerous forms of social damage. Specifically, many registered sex offenders experience stigmatization, which can lead to ostracism by community members. As a result of active demonstrations of contempt by community members, many publicly identified sex offenders report persistent feelings of vulnerability, undergo heightened levels of stress, and witness harm to their family members. It is common for individuals who are publicly identified as sex offenders to struggle with maintaining relationships and developing new associations. Once individuals are put on publicly accessible registries, many of their friendships are lost altogether, and the quality of the few relationships that persist may be greatly diminished. Registered sex offenders tend to internalize their spoiled identities as a result of their social exclusion and intentionally withdraw from community involvement, which further reduces their social support. Moreover, it is not uncommon for convicted sex offenders to lose their jobs when coworkers and employers discover their status from PORs. The loss of housing and need to locate to a new residence are also common experiences for sex offenders who have been discovered through PORs.

PORs may also negatively impact individuals other than convicted offenders who are placed on such databases. People who reside in neighborhoods where convicted sex offenders live can lose monetary value in their homes when PORs show that such offenders reside nearby. Police departments, probation and parole agencies, and other government entities may be deprived of time, money, energy, and other resources when they are responsible for implementing and maintaining PORs. In addition, family members of individuals

who are publicly identified as sex offenders may experience negative repercussions, including chronic hopelessness, depression, frustration, stress, shame and embarrassment that prevent them from participating in community activities, and deterioration and loss of social relationships. Children of convicted sex offenders on PORs may be treated differently by teachers and other children at school and frequently cannot have their POR parents attend school events.

Other Criticisms

Examinations of SORN laws also show other limitations of PORs. In theory, PORs are supposed to help stop victimizations by strangers through the release of their identities and whereabouts. However, individuals known to victims are generally most likely to commit offenses against them. As a result, PORs may give community members a false sense of confidence regarding their safety. At the same time, PORs may contain inaccurate or misleading information, due to errors, incomplete data, outdated records, or other issues. A significant number of profiles on the Florida Sexual Offenders and Predators Registry and Kentucky Sex Offender Registry were found to have contained incorrect or missing information. Such incomplete or invalid data make the identification of convicted offenders and their whereabouts nearly impossible. Furthermore, PORs are not comprehensive lists of criminal offenders. Many offenders are neither detected nor successfully prosecuted. Some may avoid public exposure through plea agreements or because their criminal offenses do not obligate them to register. Others simply may not adhere to registration requirements. Moreover, there is evidence that PORs may be incredibly expensive to establish, implement, and maintain.

Newest Developments

Although PORs in the past several decades almost exclusively centered on convicted sex offenders, they are becoming increasingly focused on additional types of lawbreakers. Suffolk County, New York, in 2010, enacted what is believed to be the first publicly accessible registry aimed at animal abuse offenders. In January 2016, Tennessee went

live with the first statewide animal abuser registry. In addition, the Drug Offender Registry Database in Tennessee and the Convicted Methamphetamine Manufacturer Registry in Illinois are recent examples of PORs that target convicted drug offenders. Despite their flawed premise, lack of effectiveness, and harmful nature, PORs will likely persist as the public and lawmakers continue to call for and perceive them as important ways to address criminal behavior.

PUNISHING SMARTER PROGRAMS

The concept of *punishing smarter* is often used to describe deterrence-based initiatives. During the get-tough movement of the 1980s and 1990s, these included popular strategies such as boot camps, three strikes and you're out policies, and mandatory minimum sentences for drug offenders. Although the aforementioned sanctions and initiatives have been criticized for not having a

significant impact on crime rates, deterrence-based policies have not lost their favor. There are a number of reasons these initiatives endure, but it is partly attributed to the fact that they often rely on commonsense strategies that are politically popular. Regardless, their persistence is perplexing in light of the vast literature regarding the limits of punitive-based strategies and the promise of the Risk-Need-Responsivity (RNR) model as an alternative. This entry discusses the limits of punishing smarter programs and argues that they will likely continue to fail, if they do not utilize empirically driven strategies shown to be effective in changing offender behavior.

Managing Behavior Through Punishment

The get-tough movement of the 1980s ushered in a myriad of punishment-oriented strategies based on both retribution and deterrence. Popular strategies at the time included boot camps and tougher mandatory minimum sentencing laws, with the former focused on severity of punishment and the latter on certainty. The popularity of these strategies is not surprising given they relied on commonsense ideology. The boot camp, for example, relied on challenging offenders physically and providing them with the discipline they seemed to lack in their own lives. Although tremendously popular for a time, studies found that boot camps not only were ineffective, they produced worse outcomes for many of the individuals subjected to them.

In the 1980s, Congress enacted a variety of mandatory minimum sentences, most commonly directed at drug offenders. Mandatory minimum sentencing laws sought to remove much of the judicial discretion used at the point of sentencing and intended to increase the certainty of punishment. Critics, however, argue that these policies disproportionately impacted minorities, further disadvantaged communities, and simply shifted discretion into the hands of prosecutors. Perhaps most important, however, was the impact that these laws had on the incarceration rate, which was considered too costly and not sufficiently effective. By early 2000, states began passing legislation to repeal or amend these statutes. This shift has become part of a broader refocusing on community corrections as a reasonable, and cheaper, alternative to incarceration. The interest

in community corrections, however, has led to a number of initiatives around the best way to manage and supervise offenders. One such example is the Hawaii Opportunity Probation with Enforcement project.

Project Hawaii Opportunity Probation with Enforcement was conceived in 2004 as a means of increasing the certainty of punishment for probationers who violate their conditions of supervision. The project was conceived by a judge who felt that probationers were not always being held accountable for their behavior due to the procedures and processes required to invoke sanctions. As a result, he created a collaborative process that involved probation, law enforcement, and the prosecutor's and public defender's offices.

At the program's core is a graduated sanctions approach. Probationers are informed that violating conditions of their probation will result in immediate arrest, jail time, and possibly prison time if they continue to violate these conditions. The program targeted higher risk probationers and those who have struggled with traditional probation in the past. In his 2013 essay, "Smart on Crime," Mark Kleiman argues that these types of initiatives work because people commit crime due to poor decision-making. In a 2015 publication, Kleiman suggested that the solution must include deterrent-based strategies that will reduce crime among those who are impulsive and reckless. He continues by arguing that drug testing combined with swift and certain sanctioning could hold offenders accountable while delivering a similar effect to incarceration.

The notion of holding offenders accountable is not new. That basic message was pervasive during the get-tough movement of the 1980s and 1990s and persists today. Even countries less punitive than the United States have adopted some of these principles. For example, Paul Gendreau and colleagues note that Canada and England have argued for an *accountability agenda* in corrections. This contends that offenders can be motivated through a structured reward- and consequence-based approach. However, the use of certain and swift punishment utilized in the Hawaii Opportunity Probation with Enforcement model misses an important point. Sanctioning behavior, regardless of its certainty or swiftness, may teach the offender in the short term to avoid certain behaviors. This

has, however, little impact on long-term behavior since it does not address the person's criminogenic needs.

Managing Behavior Through Treatment

Alternatively, studies suggest that long-term change is achievable by focusing on the principles of risk, need, and responsivity (the RNR model). To illustrate, the RNR model was applied to community supervision officers to encourage their role in the offender change process. An analysis of audiotaped interactions between 62 Canadian probation officers and their clients found that officers did not follow the RNR principles. In response, Jim Bonta and colleagues created a training program for community supervision officers called *Strategic Training Initiative in Community Supervision*. The training program was designed to provide officers with a background in the RNR model and core correctional practices and to teach them skills they could use in their one-on-one sessions with clients. Using a randomized control design, they found that clients who were supervised by officers utilizing the Strategic Training Initiative in Community Supervision approach (particularly the cognitive techniques) were significantly less likely to recidivate compared to controls. Other studies support training community supervision officers and find that offenders supervised by officers trained in core correctional practices were less likely to recidivate.

Researchers at the University of Cincinnati developed a similar approach for both juvenile and adult probation/parole agencies referred to as the *Effective Practices in Community Supervision* model. As with the Strategic Training Initiative in Community Supervision protocol, officers are trained in core correctional practices and encouraged to provide brief skill-based interventions to probationers during their client meetings. Preliminary research findings of the Effective Practices in Community Supervision model are similar to those mentioned above with trained supervision officers performing better than untrained officers.

Therapeutic models that teach community supervision staff to provide therapeutic interventions over a sanctions-focused approach all have one thing in common: They advocate for an environment that supports offender change. Utilizing theoretically

informed and empirically supported treatment strategies, rather than deterrent-based ones, is a smart approach.

PUNISHMENT

The words *crime* and *punishment* are inexorably associated in the common lexicon. It is considered a given that those men and women who transgress against the laws of the land, whatever that land may be, will be punished in keeping with local laws. A large slice of the public purse is spent to fund the agencies responsible for the apprehension, trial, and eventual punishment of those convicted of a crime. What might we, the taxpayers,

expect in return for this expenditure? In other words, why punish?

The textbooks of many disciplines, including criminology, economics, law, philosophy, psychology, and sociology, give accounts of theories that seek to explain why punishment is a justifiable response to criminal behavior. These justifications for punishment are taken to be *deterrence*, *retribution*, *rehabilitation*, and *incapacitation*, each with their own particular ways to consider their effectiveness.

Deterrence

General Deterrence

If punishment is a likely consequence of crime, it follows that the population at large should be deterred from committing crimes in order to avoid being punished. The effectiveness of this proposition is arguably reflected in national crime rates: If punishment is seen to be done, then the crime rate should remain reasonably constant. However, the rate at which crimes are committed are subject to many diverse influences, such as levels of employment and demographic fluctuations; so that in the main, the national crime rate is a blunt measure of criminal justice practice. The general deterrent hypothesis has been tested using the special case of the death penalty. A pre-post effect can be calculated for countries that abolish the death penalty or, as with New Zealand, where over a period of years the death penalty is abolished, brought back, and then finally abolished. The complexities of the analyses, necessarily spanning long periods of time, have produced conflicting findings regarding the presence and size of any deterrent effect of capital punishment.

A counterpoint to general deterrence is that people obey the law not out of fear of punishment but for entirely more positive reasons: We may agree to comply with a social contract in which we respect each other's property, we morally agree that violence against other people is not acceptable, and we hold that human life is sacrosanct.

Special Deterrence

In special deterrence, the focus shifts from the general population to the individual offender. The

theory holds that once punished, the individual criminal will be deterred from committing more crimes lest he or she receives further punishment. This hypothesis can be tested by looking at the rates of reoffending of known offenders. It is known that reconviction rates published by governments vary according to variables such as type of offense, age of offender, and drug use. Thus, for some property offenses, the reconviction rate may be as high as 80%, whereas for first-time juvenile offenders, the rate is considerably lower at around 25%. The elevated levels of reconviction for high-volume crimes such as burglary and some serious violent crimes against the person inevitably lead to calls for ever harsher punitive measures such as longer prison sentences, austere prison regimes, and the return of capital punishment.

Retribution

Sometimes referred to as *just deserts*, the delivery of retribution for the wrongly committed rests on the principle of *lex talionis*, an eye for an eye, a tooth for a tooth. For centuries, all crimes were met with the most severe of punishments including mutilation, deportation, and death by terrible means such as crucifixion and slowly being crushed. However, now it is understood that the severity of the punishment should not be cruel and that it should be in proportion to the crime. In its purest form, the argument for retribution seeks no other consequence than the delivery of the appropriate retributive measure, be it a fine or imprisonment. The effectiveness of retribution is gauged by the perceived degree of appropriateness between crime and punishment. The fit between a given punishment for a specific crime will always be a matter of debate influenced by the public values of the time and by exceptional individual cases. An example of the latter point is found in the 1993 UK case of the murder of a 2-year-old boy by two other young boys, both aged 10 years. This incident precipitated widespread discussion not just of the appropriate punishment for such young children but also wider questions about the type of society and the values it holds in which such an event can occur.

Those who favor retribution and wish to be tough on crime may argue for harsh punitive measures such as the death penalty for murders,

austere prison regimes, and military-style boot camps for persistent young offenders. The counterposition sets store by different values such as the sanctity of life, the possibility of wrongful executions, and the recognition that some of those who commit crimes need supportive, not punitive, criminal justice policies.

Rehabilitation

The great liberal reformers, typified by figures such as Elizabeth Fry (1780–1845) in the United Kingdom and Enoch Cobb Wines (1806–1979) in the United States, campaigned for humane prison conditions in order to reform prisoners and so help them return to society. This emphasis on positive change for prisoners, now called *corrections* in some parts of the world, led to the introduction of a range of measures intended to help offenders during their period of punishment. The nature of these rehabilitative measures has varied over time, partly as a result of changing beliefs and partly because of the findings of empirical research.

The early reformers held great store by the rehabilitative properties of education, particularly reading, and religion. The enduring nature of one of these pillars of rehabilitation is evident in a 2015 court case ruling, which followed the UK Justice Secretary banning books for prisoners as part of a crackdown on their *perks and privileges*. The ban was challenged in court and overturned with the judge remarking that “[a] book may not only be one which a prisoner may want to read but may be very useful or indeed necessary as part of a rehabilitation process.”

Alongside initiatives such as training for employment, rehabilitative efforts have also embraced a range of psychological interventions. Over the years, the *treatment approach* has followed the major psychological theories, ranging from psychotherapeutic to behavioral interventions. Large-scale rehabilitative initiatives—offending behavior programs—are evidence-based in that their design follows the findings of a series of meta-analyses which detailed *what works* in reducing offending. The evaluations of offending behavior programs are favorable in showing a reduction in reconviction when they are delivered to a high standard.

Incapacitation

The punishment of offenders through prolonged incapacitation, a contemporary echo of deportation, is based on the notion that if enough offenders are removed from society for lengthy periods of time, the public will be protected and the crime rate will fall. The burgeoning prison population in the United States, which the U.S. Bureau of Justice Statistics reported as 2,220,300 adults in 2016, is an inevitable consequence of laws such as *three-strikes laws* whereby offenders convicted under this law serve a mandatory life sentence. A prison population on scale noted is not only very expensive but poses a risk of overcrowded institutions as it continues to grow. An increase in numbers of prisoners leads to a deterioration in conditions, including overcrowding with attendant problems of prisoner riots. Yet further, a population of older adult prisoners place new demands both on the physical nature of the prison and the skill sets of prison staff. One solution is to build more prisons, so consuming more of the public purse, in order to incapacitate more and more criminals. Another solution is to use selective incapacitation targeted at, say, high-frequency offenders.

Does incapacitation reduce the crime rate? Given the usual caveats with analysis of national statistics, it appears that incapacitation does reduce the crime rate. The size of the reduction is contingent upon the country for which the crime rate is under investigation and in disentangling the effects of any rehabilitative measures used during imprisonment.

Populism

Elections to political office are not typically won by promises of being soft on crime. The inevitable rhetoric of parties standing for election, often reinforced by media surveys of popular opinion, is once in government they will be tough on crime. This toughness will be demonstrated by unfailingly using the government's power to punish and by promises to bring in new laws to enhance this punitive power. In contrast to this parochial position, in 1910, when he was Home Secretary in the UK government, Winston Churchill remarked that the public's views on the treatment of criminals is "one of the most unfailing tests of the civilization of any country."

A mark of a civilized state is found in the way in which it treats its less fortunate members, including those it chooses to punish. There are exceptions in who the state elects to punish.

Exceptions

The first group excluded from state punishment are those under the age of criminal responsibility. In jurisdictions that espouse the notion of *mens rea*, an individual cannot be said to be responsible for their actions until they have reached an age at which they have the mental capacity to know right from wrong. The age of criminal responsibility varies across countries; for example, in Scotland, it is 8 years whereas in Belgium it is 18 years.

The second group commonly excluded from punishment are those individuals who have a mental health disorder. The exact nature of a disorder that leads to exclusion from the criminal law, defined in a given country's mental health law, typically includes mental illness, personality disorder, and intellectual disability.

Effectiveness

Is punishment effective? If the aim is retribution, then punishment arguably achieves its aim: The debate is whether, in terms of quantity and quality, there is enough punishment and whether it is of sufficient severity. A similar position applies with incapacitation: Locking offenders away may serve a purpose, but are offenders being removed for long enough? While it is difficult to gauge the effectiveness of punishment as a general deterrent, it has little effect as a specific deterrent in motivating offenders to change their behavior. The paradox of attempting to bring about positive change in offenders while at the same time punishing them for their crime is probably not the optimum conditions for rehabilitation. The evidence is in favor of treatment in the community rather than in security.

The parameters of effective punishment in terms of changing behavior are well established in the research literature. To be effective in reducing criminal behavior, punishment would need to be *certain*, which it is not; delivered *close in time* to the offense, which does not happen; and delivered initially at *maximum intensity*, which it again is

not. It is also worth noting that once punished, the majority of offenders will return to the same communities—the same social and economic conditions, the same families, the same peer group, and the same availability of alcohol and drugs—in which their crimes were committed. Save for the immediate pains of retribution and incapacitation, arguably ends in themselves, it would be a powerful punishment that had any substantial long-term (specific) deterrent effect set against such environmental forces.

PUNISHMENT, EFFECTIVE PRINCIPLES OF

Principles of punishment refer to the organizing philosophies that guide responses to deviant behavior. Traditionally, four dominant penological principles influence sentencing and sanctioning in the criminal justice system: retribution, deterrence, incapacitation, and rehabilitation. Each of these principles proposes different ideas regarding

why a person commits crime and what consequences it has for society; therefore, each principle recommends different mechanisms for responding to an offense. While occasionally correctional sanctions can retrospectively influence the understanding of these principles, it is more often the case that forensic practitioners and criminal justice agencies begin with a theory and then aim to manifest those ideas into practice and policy.

In estimating the effectiveness of these principles of punishment, it is important to note that the usefulness of any of these theories is dependent on the goal (which may in fact be specified by the principle itself). Thus, whether a punishment *works* is a matter of the principle's blueprint for punishment; is the punishment meant to get even with the criminal (retribution), discourage the decision to commit crime (deterrence), limit the ability to commit crime (incapacitation), or minimize the propensity to commit crime (rehabilitation)? Each of these leading principles of punishment is effective in some ways but not in others, as punishments are generally not designed to embody multiple penological ideals simultaneously. However, it is quite common for correctional practices (e.g., imprisonment) to exhibit some degree of overlap in these punishment principles, meeting different goals in different ways and at different times.

This entry describes the four central principles of punishment: retribution, deterrence, incapacitation, and rehabilitation. The section on each of these principles provides an overview of the foundational concepts, a brief description of any relevant theoretical advances, a few illustrations of how the principle is applied in the criminal justice system, and an overview of the research evidence that supports or moderates the use of that principle.

Retribution

Retribution simply proposes that committing a crime demands commensurate punishment. Based on the adage “an eye for an eye,” retribution requires that the harm caused by a crime must be weighted with adequate suffering of the offender in order to rebalance the scales of justice. Retribution is a nonutilitarian principle of punishment, meaning that it does not have concerns of

ensuring the greatest good for the greatest number of people (unlike the other three principles of punishment that have the higher level goal of utility or benefiting the majority). Crime control is not a concern of retribution, nor are understanding and accommodating the circumstances that lead to offenses. The only consideration of the theory is that the punishment fits the crime, ensuring that petty thieves are not sanctioned in the same way as rapists, for example. The theory of retribution has been adopted under the *just deserts* model, a simple approach to punishment that purports that all offenders are treated equally and will be punished in accordance with the recommended sentence attached to their unlawful action.

Determinate sentencing is a contemporary application of retribution. Sentences are specified in legislation and dictate the appropriate punishment corresponding to the crime. The aim here is that punishment is transparent and applied to offenders equally, without consideration of their circumstances. Sentencing guidelines are another manifestation of retribution, providing judges with a matrix to base the sentencing decision. Judges cannot go outside of sentencing guidelines except under extreme circumstances and then their reasons must be documented. Retribution opposes judicial discretion. While advocates of determinate sentencing suggest it provides simple and equal justice, it assumes the individual's free will to engage in criminal activity, an assumption not supported by research. Many risk factors for criminality are not chosen by the individual but are forced upon them, such as low IQ, abuse, unfavorable household circumstances, and neighborhood characteristics. Therefore, the free will to commit crime required to ensure retribution is a *just* form of punishment and is not supported by science. However, retributive policies remain popular, as these punishments satisfy a thirst for vengeance and promote equity.

Deterrence

Deterrence theory is based on the notion that people are inherently self-serving and seek to maximize pleasure and minimize pain. According to the principle, crime is committed when the

perceived benefits outweigh the potential costs. The purpose of punishment is therefore to increase the cost associated with crime in order to *scare straight* or deter the would-be offender. Efficacy of deterrence is dependent on the certainty, severity, and swiftness of punishment. Deterrence can be separated into general and specific forms. General deterrence refers to the effect punishment has on wider society when an example is made of an offender; seeing someone receive a sanction reinforces the consequence of crime and may convince others not to engage in similar behavior. Specific deterrence is limited to the individual offender being punished; the effect of punishment in this case is to discourage the offender from repeat offending.

The principle of deterrence is based on rational choice theory, which proposes that crime occurs when a cost-benefit analysis takes place prior to offending, and the benefit of offending is perceived to outweigh the cost. The theory assumes that crime is a choice, and people are capable and rational decision makers. Contemporary applications of deterrence are often based on increasing the severity of punishment, seen in the *get tough* movement, which aims to raise the cost associated with crime and therefore affect the decision-making process. Examples of such applications include boot camps, mandatory sentencing, zero tolerance policies, and three-strikes laws. There is anecdotal evidence of punishment having a general deterrent effect, given the fact that most people do not commit crime, and many cite fear of punishment as part of their reasoning. However, there is limited empirical support for severe sanctions (e.g., parole revocations, long imprisonment terms) reducing individual recidivism. Furthermore, punitive correctional interventions such as boot camps and harsh prison conditions have shown no evidence of decreasing recidivism and, in some cases, increase reoffending. Some studies suggest that sanction certainty is more influential in discouraging crime, that perceptions of risk may matter more than actual risk, and informal sanctions (e.g., shame) can deter as much as formal punishments (e.g., arrest). Yet collectively, research findings question the ability of punishment-oriented programs to reduce offending.

Incapacitation

The aim of incapacitation is to prevent crime by restricting the freedom of the offenders and therefore their ability to engage in further criminal activity. Incapacitation is future oriented, as it does not have concerns with correcting crimes already committed; it means only to prevent reoffending through *caging* but not *changing* offenders. There are two approaches to incapacitation: collective and selective. Collective incapacitation is broad in application and involves consistent sentencing of each offender who meets specific criteria, such as conviction of a certain crime or number of offenses (e.g., locking up all drug suppliers). In contrast, selective incapacitation aims to target only the most persistent or dangerous offenders for punishment. Offenders considered to present a high risk of recidivism are detained longer and in some cases indefinitely.

Contemporary incapacitation takes several forms. It can be achieved through electronic tagging, supervision orders, and home detention, all of which limit freedom of movement. Capital punishment is the most extreme illustration of incapacitation, while incarceration is the most commonly considered form of the principle. Mass imprisonment demonstrates a strong commitment to incapacitation as a penal policy across Western democracies. Selective incapacitation is utilized in the preventive detention of prolific sexual and violent offenders who are considered too dangerous to release back into the community. Anti-terrorism laws often also apply selective incapacitation as a means of preventing potential crime. Empirical support for incapacitation is dubious. Research illustrates that imprisoning offenders does prevent numerous crimes from taking place, yet these findings are misleading, since studies compare the result of imprisonment with taking no action at all. Although there does appear to be a small incapacitation effect, future research is needed to consider the effect of imprisonment versus alternative sanctions to provide a more reliable indication of efficacy. Empirical support for selective incapacitation is difficult to obtain given the impossibility of determining whether future

offenses would have taken place had the individual not been detained. Selective incapacitation is subsequently surrounded with issues of accurate risk prediction, ethical dilemmas, and human rights concerns.

Rehabilitation

Rehabilitation involves the administration of interventions with the aim of reducing recidivism by treating the offender. Interventions are designed to address the factors responsible for causing the offending and are delivered in a correctional setting. Rehabilitation is concerned with reducing crime in a socially conscious way, by correcting the individual offender while they are under the supervision of the criminal justice system. Rehabilitation is different from retribution, incapacitation, and deterrence in its pursuit of identifying the problem and then treating it. Principles for effective treatment programs have been discovered, resulting in the Risk-Need-Responsivity model being developed to guide interventions. The model stipulates that intervention will be most successful when administered to the highest risk offenders, targeting only empirically supported and changeable factors for criminality, and tailored to the individuals' learning style, abilities, and motivations.

Cognitive skills programs are widespread in rehabilitative interventions. Such programs enhance problem-solving, decision-making, self-control, and other interpersonal skills linked with offending behavior. Other contemporary interventions include programs specifically for sex and violent offenders or target domestic violence, anger management, drug and alcohol dependence, victim awareness, female offenders, and indigenous offenders. Research concludes that imprisonment without effective treatment does not reduce recidivism and, in many cases, increases recidivism. There is vast empirical data demonstrating that evidence-based interventions reduce recidivism when comparing treated to untreated offenders. Programs based on the Risk-Need-Responsivity model in particular show even greater effects in decreasing reoffending. However, there is no miracle treatment program that is one-size-fits-all, and there is often slippage

between well-designed rehabilitation programs and routine delivery of those interventions. Yet importantly, the literature concludes that the key to effective rehabilitation is no longer finding out what works but to determine what works best for whom and under what conditions.

Effective Punishment

Whether a punishment is *effective* is tied to the goal of that program or policy, and the goal is often embedded in the principle that motivated that punishment. A punishment can fulfill a number of principles at once, although each has a unique mechanism of action and desired outcomes. Indeed, correctional sanctions are often designed with one principle in mind (e.g., repay, discourage, disable, or treat), although the effects of that punishment may be interpreted differently depending on the preferred theory of the inquiring camp. Moreover, these principles do not operate in a vacuum but are constrained by culture, politics, economics, and humanitarian concerns; theories of punishment wax and wane in application and effectiveness in part as a reflection of social climate. Although there are some emerging penological philosophies (e.g., managerialism, therapeutic jurisprudence, restorative justice), the core punishment principles of retribution, deterrence, incapacitation, and rehabilitation have dominated

correctional practices for centuries and will likely continue to do so for some time. While each is effective in its own right by meeting the goals specified within the theory, a canon of research demonstrates that in regard to the universal goal of reducing crime, the most effective principle of punishment is rehabilitation.

RACIAL BIAS IN CRIME POLICIES AND PREVENTION

See Bias in Crime Policies and Prevention

RACIAL PROFILING

Racial profiling in law enforcement is the practice of stopping, searching, or arresting a suspect based on racial characteristics on the assumption that members of minority racial or ethnic groups are more likely to commit certain crimes. There is general agreement that race alone cannot be a basis for a stop or search but that race can be considered where one's race matches a description of a perpetrator. There is sharp division, however, on the question of whether limited use of race should be permitted in the assessment of cause to stop, search, or arrest, and on the appropriate benchmarks for determining whether statistical disparities are explainable by nonracial factors.

Historical Context

Racial profiling is a relatively recent formulation of race-based practices, of which there is a long history in the United States. Slavery, Jim Crow laws, and private acts of racial exclusion and violence, including lynchings, marked almost two centuries of the United States' history as a nation. Immigration laws have often excluded non-Whites and

avored those of European origin. The notorious Palmer Raids, conducted by the U.S. government following World War I in response to isolated acts of terrorism, subjected ethnic and religious minorities to deportation. Perhaps the most notorious act of racial profiling occurred during World War II with the internment of more than 100,000 persons of Japanese descent on the claim that they presented a national security threat. Now regarded as an indefensible policy, this program was upheld by the Supreme Court in *Korematsu v. United States* (1944).

With the successes of the civil rights movement in the 1960s and 1970s and the country's turn toward racial equality, there was a growing legal and political consensus that racial profiling was unconstitutional and counterproductive as a law enforcement tool. These practices were strongly criticized by President Bill Clinton, who condemned the practice as *morally reprehensible*, and by the candidates during the 2000 presidential election campaign. Racial profiling has also been an issue with respect to many other areas of social and economic relationships, including housing, employment, and lending practices; however, these issues are outside the scope of this entry.

The Data

The attention to racial profiling in the 1990s was sparked in part by studies that cited the pervasiveness of the phenomenon of *driving while Black* and related race-based police practices. For example, in New Jersey, litigation and a report by the state's Attorney General showed that drug

interdiction efforts on the New Jersey Turnpike were racially disproportionate. The data showed that 15% of all drivers on the turnpike were African American and that almost all drivers violated traffic laws. Yet 42% of all stops and 73% of all arrests on the turnpike were of African Americans. Significantly, radar stops for speeding (which are race blind) were consistent with the racial driver data, while discretionary stops by troopers were twice as frequent for African Americans. Traffic stop studies in Maryland, Florida, and Illinois found patterns of stops and arrests that were also disproportionate by race.

However, statistical evidence must be carefully analyzed to determine whether racial profiling or other nonracial factors explain any disparities. Factors such as crime rates, police deployment patterns, enforcement priorities, and social and economic factors may explain statistical disparities. Thus, some law enforcement officials and scholars have argued that racially disparate impacts of policing do not reflect intentional race discrimination; rather, they are the function of higher crime rates by African Americans, the legitimate placing of more police in high-crime minority neighborhoods, and the need for aggressive policing where criminal conduct (e.g., drug dealing) is done in public areas, as opposed to private residences or college dorms. Moreover, these tactics are credited by some for the large drop in crime over the past 20 years.

Are these views—that African Americans commit a disproportionate number of crime and therefore that race is a legitimate factor in deciding who of a large number of persons to stop or investigate—consistent with empirical evidence or constitutional doctrine? There is good reason to question both of these assertions. First, in the War on Drugs, studies that track drug possession and usage find scant differences based on race. Furthermore, there is no firm evidence that those who distribute or traffic in illegal drugs are more likely to be African American. The racially disparate stops on the New Jersey Turnpike and on Maryland highways yielded seizures of drugs that were comparable by race, yet far more Black drivers were stopped than White drivers. In some locations, Whites were more likely to be in possession of drugs. Yet 37% of those arrested, 55% of those

convicted, and 74% of those incarcerated for drug offenses were Blacks.

Second, there is now evidence of racial profiling in stop and frisk policing. In *Floyd v. City of New York*, a federal court ruled that the stop and frisk practices of the New York Police Department over the period 2004–2012 were intentionally racially discriminatory. The court found that of the over 4 million stops, minorities were stopped at a rate almost double their population while Whites were stopped at rates less than one third of their population share. Regression analysis that took into account crime rates by race, police deployment, and social and economic factors or differing neighborhoods failed to explain these highly disparate rates. Furthermore, the court cited training and supervision practices that urged officers to focus on Blacks. Similar studies of stop and frisk practices in Los Angeles, Philadelphia, Baltimore, and Chicago have found similar patterns of race-based policing.

The racial profiling debate has also focused on the issue of mass incarceration. As of 2017, with 5% of the world's population, the United States has 25% of the world's prisoners, with over 2.2 million inmates being held in U.S. prisons and jails and millions more under parole or probation supervision. This is an increase of over 7 times the number of prisoners as late as the 1970s and far more than any other industrialized country. Black males are 6% of the U.S. population but over 40% of prisoners in the United States; it is estimated that one in every three Black men can expect to serve some time in a jail or prison. Crime rates by race may explain part of the statistical disparities, but many argue that the large disparities are not fully explainable by nonracial factors.

Similarly, the number of Black men killed by police far exceeds their share of the population. The increasing number of video-recorded police shootings and the deadly attacks on police have ignited another racially charged debate on policing. As the governor of Minnesota, Mark Dayton, stated in 2016 after viewing a police shooting, "Would this have happened if the driver and passenger were white? I don't think it would have" (Swaine, Laughland, & Beckett, 2016). If race is a factor, is it a result of implicit bias, whereby police, like many other people of all races, process information, observations, and reactions through a

racial lens, often with some experiences or knowledge that influences their beliefs, with no intent to engage in discriminatory behavior?

Starting after the attacks of September 11, 2001, and with subsequent terrorist attacks in the United States, the debate on racial profiling has become a significant fault line in the U.S. politics and legal system. Those who advocate that special attention, surveillance, and other investigative methods should be focused on Muslims and Islamic communities assert that to do otherwise ignores the fact that so much terrorism is a product of religious and ethnic loyalties and beliefs. Race considerations are urged on the grounds that threats to national security are too great and the relationship between ethnicity and nationality is too strong to ignore. The relationship between terrorism and race and ethnicity is an especially contentious issue, especially in view of terrorist acts by persons of all races, religions, and ethnic backgrounds.

The 2014 U.S. Department of Justice Official Guidance for Federal Law Enforcement Agencies Regarding the Use of Race, Ethnicity, Gender, National Origin, Religion, Sexual Orientation, or Gender Identity provides the following metrics for terrorism and related investigations:

In making routine or spontaneous law enforcement decisions, such as ordinary traffic stops, Federal law enforcement officers *may not use race, ethnicity, gender, national origin, religion, sexual orientation, or gender identity to any degree*, except that officers may rely on the listed characteristics in a specific suspect description. This prohibition applies even where the use of a listed characteristic might otherwise be lawful.

In conducting all activities other than routine or spontaneous law enforcement activities, Federal law enforcement officers *may consider race, ethnicity, gender, national origin, religion, sexual orientation, or gender identity* only to the extent that there is trustworthy information, relevant to the locality or time frame, that links persons possessing a particular listed characteristic to an identified criminal incident, scheme, or organization, a threat to national or homeland security, a violation of Federal immigration law, or an authorized intelligence activity. In order to rely on a listed characteristic, law enforcement offi-

cers must also reasonably believe that the law enforcement, security, or intelligence activity to be undertaken is merited under the totality of the circumstances, such as any temporal exigency and the nature of any potential harm to be averted. This standard applies even where the use of a listed characteristic might otherwise be lawful. (Emphasis added.)

Critics of this distinction make several points. First, terrorists are not from a single ethnic group. Richard Reid, known as the Shoe Bomber for attempting to ignite an explosive device in his shoe while aboard a transatlantic flight in 2001, did not meet this profile, nor did the 1995 Oklahoma City bombers, White supremacists who have targeted African Americans, or those who have killed abortion providers. Second, even if the statistical approach is valid and that most of the terrorism is committed by Islamic fundamentalists, the field of possible suspects is so large that the central problem of racial stereotypes remains. Assume, for example, that 90% of terrorist activity is committed by 100 persons in an ethnic group of 1 million persons. That leaves 99.9% of the group as innocent but still subject to enhanced surveillance, stops, and searches. Others have contended that to the extent a community believes it is unfairly targeted by stereotyped investigations, it may be less willing to cooperate with law enforcement and to provide the intelligence about persons planning criminal acts.

The Constitutional Debate

The U.S. Supreme Court has ruled that stops, searches, and detentions cannot be justified *solely* by racial factors, but in the immigration context has permitted race or ethnicity as a permissible factor in border patrols and at border checkpoints. The Court has not addressed the constitutionality of racial factors in terrorist investigations, but it is likely that it would permit at least some consideration of race and ethnicity where the racial factor appears to be linked to credible intelligence information. Moreover, the Court has held that the Fourteenth Amendment to the U.S. Constitution forbids only intentional racial discrimination; disparate impact on racial groups of otherwise race-neutral laws is not unconstitutional. Even with

respect to claims of intentional discrimination, the Court has imposed high barriers to the use of statistical evidence to prove discrimination. Finally, in *Whren v. United States* (1996), the Court ruled that pretextual traffic stops (i.e., where the driver committed a traffic violation but was stopped because of his race) did not violate the Fourth Amendment's proscription on unreasonable searches and seizures, a ruling that has been subject to strong criticism.

The political and legal debate on racial profiling is likely to extend as well to new technologies. In the 21st century, with the advent of big data, social scientists and statisticians have developed complex algorithms to attempt to predict future behavior. These risk assessment tools are being used in the criminal justice system in the setting of pretrial bail, in sentencing proceedings, and in determinations on parole of offenders. These tools are also being used to predict future criminal conduct by geographical locations, community social and economic factors, and past crime patterns. Once again, the issue of bias has been raised: Are any of the predictive factors that are part of the algorithms based on or integrally connected to race?

The United States has a long history of racial conflict and discrimination. It also has a recent history of laws and movements to ensure racial equality. In this process, there is an unresolved issue of the use of race and ethnicity in criminal investigations and especially in the investigation of terrorism. What some denigrate as racial profiling others champion as smart and effective law enforcement. The courts, the legislatures, and the public will continue to debate these issues on legal and moral grounds.

RACKETEER INFLUENCED AND CORRUPT ORGANIZATIONS ACT

The U.S. Congress enacted the Racketeer Influenced and Corrupt Organizations Act of 1970 (RICO) to deal with group crime, including organized crime, white-collar crime, violent groups, terrorism, and street gangs. RICO is the federal prosecutors' tool of choice to deal with sophisticated forms of crime and an effective mechanism for prosecutors and crime victims to secure comprehensive civil relief. This entry considers effective law enforcement for group crime, the elements of RICO, and RICO in use.

Effective Law Enforcement

Effective law enforcement requires substantive provisions, procedural provisions, administrative organizations, and personnel. Without these, the law will be ineffective in dealing with group

crime. Statutes, too, are only one part of a criminal justice system. Without important provisions (e.g., dealing with process, statutes dealing with false testimony, witness protection programs), RICO legislation is not effective.

The provisions of most older criminal codes are inadequate to deal with group crime, whether organized crime (e.g., Mafia families or similar groups), white-collar crime (e.g., securities fraud, antitrust violations), violent crime groups (e.g., White hate, anti-Semitic), terrorism, or street gangs. Legislators envision a particular form of crime when they write criminal codes. Traditionally, they envision isolated offenders engaging in isolated criminal offenses. These offenses (e.g., murder, rape, robbery) usually occur on the streets of major metropolitan areas or within family dwellings. Most murders, for example, occur within a family or romantic relationship. They involve a limited number of people and are often crimes of insanity, passion, or behavior affected by the use of alcohol. In comparison, Mafia hits, for example, are done impersonally. Most rapes, however, occur between individuals who have some prior relationship, and rape committed by a stranger is less frequent. Most robberies occur in population centers on the street or in commercial establishments and are repeat offenses. Drafting a criminal code to address these offenses is exactly what traditional statutory drafters know well. Dealing with groups of criminals, however, requires drafting sophisticated laws.

Criminal groups present a challenge for law enforcement beyond traditional offenses or offenders. In fact, law enforcement has not been effective using traditional tools in dealing with criminal groups, such as the Mafia. Legislators did not design law enforcement agencies, prosecutor offices, criminal codes, criminal procedures, or rules of evidence with the Mafia in mind. If law enforcement is to successfully curtail such groups, they face formidable hurdles. They must obtain evidence of past offenses, even if witnesses are not available because of fear of retribution. Prosecutors must convict individual persons of specific offenses but must also consider the relationship between individual offenses and a possible group behind it and connect multiple individual offenses. Organized criminal groups commit ongoing offenses; they are also prone to commit cognate offenses. For

example, an organized crime group might not only deal with illicit drugs but also commit murder or use other forms of violence to protect the drugs and proceeds and to monopolize the traffic area.

Law enforcement must understand the character of a group, the pattern of its offenses, and then seek to investigate and sanction them appropriately. All members of society need to see the scope of criminal offenses if the society understands them and how to protect itself from these sorts of behaviors through more effective law enforcement. The public has to support law enforcement if enforcement hopes to succeed. Law responds to the articulated wants of the public. Those wants should reflect the necessary knowledge it needs to formulate the goals of law enforcement, the means of law enforcement, and an evaluation of its successes, its failures, and the reasons behind both.

If criminal activities come before a court and a conviction results, the court should be authorized to impose severe sanctions, including long-term incarceration. Law enforcement has seldom succeeded in deterring these offenders from a life of crime or in their reformation when it captures offenders. Justice (defined in terms of deterrence, reformation, and isolation) is the collectively defined goal of law enforcement. Here, however, justice focuses more on reasonably measured incapacity for society's protection. Generally, criminals lose their day-to-day vitality to engage in most forms of crime with the mere passage of time. In the experience of most knowledgeable enforcement practitioners (officials inside law enforcement and scholars outside of law enforcement who study it), this truism is not correct in the instance of organized crime. It stands out as an exception, and because of the inability of society to achieve the other goals of justice successfully, the emphasis has to turn to incapacity. In addition, legislatures must supplement imprisonment with fines and require the forfeiture of the instrumentalities and the proceeds of the offense (or substituted assets) to make the behavior ultimately unprofitable.

The Elements of RICO

In 1970, Congress enacted the Organized Crime Control Act. Title IX is the Racketeer Influenced and Corrupt Organizations Act, codified at 18 U.S.C. §§ 1961–1968 (2012) (hereinafter *RICO*).

In Section 1961, RICO sets out relevant definitions. *Racketeering activity* includes specified offenses of (a) violence, (b) the provision of illegal goods and services, (c) corruption in labor or management relations, (d) corruption in government, and (e) commercial and other forms of fraud by, through, or against various types of licit or illicit enterprises. The term *person* includes any individual or entity capable of holding an interest in property. *Enterprise* includes any individual, partnership, corporation, association, or other legal entity and any union or group of individuals associated in fact although not a legal entity. *Pattern of racketeering* requires that the pattern reflects continuity over time and a relationship between the various instances of the racketeering activity.

In Section 1962, RICO provides standards of unlawful (not criminal) conduct. A person who receives income from a pattern of racketeering activity cannot invest or use that income in an enterprise. A person cannot get or keep control of an enterprise by a pattern of racketeering. A person employed by, or associated with, an enterprise cannot conduct the affairs of the enterprise through a pattern of racketeering. Finally, a person cannot conspire to violate RICO.

Section 1963, sets out criminal sanctions, including fines, imprisonment, and forfeiture, for a violation of Section 1962. Criminal sanctions under Section 1963 require a criminal trial instituted by the government through a grand jury indictment as well as the testing of government proof by the standard of *beyond a reasonable doubt*.

Section 1964, sets out civil sanctions, including disgorgement of illicit proceeds, and treble damages for injury to business or property, for a violation of Section 1962. Civil remedies under Section 1964 require a civil trial instituted either by the government or a private plaintiff and the testing of either government or a private party proof by the standard of *preponderance of the evidence*.

RICO in Use

Understanding RICO requires examining more than a brief outline of the substantive law. Its legal use, too, is relevant. Behind RICO are three distinct theories: (1) theory of investigation, (2) theory of trial, and (3) theory of sanction.

As a theory of investigation, traditionally, criminal investigations started with a crime and moved toward an offender. RICO begins in that fashion, but it asks more broadly focused questions. What, if any, is the relation of this offense and offender to another offender and another offense? Do the offenses form part of a pattern? What, if any, is the relation of this offender to a criminal group (an enterprise)? Did the offense produce assets? Where are they? As a theory of investigation, RICO focuses on various relations of crime to crime, offender to offender, and crime and offender to an enterprise. These investigations also trace illicit assets to seize and forfeit them. In sum, it is a theory of investigating enterprise criminality.

As theory of trial, RICO focuses on the presentation of evidence to convict an individual offender. At the same time, it broadens the trial to view enterprise as the focal point of the trial. The enterprise may function as (a) a *vehicle* (actively used by offending perpetrator), (b) an *instrument* (passively used by others without its having culpability), through which the offender(s) engaged in a pattern of offenses, (c) the *perpetrator(s)* (the offenders together exploiting a victim), or (d) a *prize* against which the offender(s) directed the pattern of offenses. The trial also focuses on the use, gain, or investing of illicit assets. In sum, it is a theory of trying enterprise criminality.

As a theory of sanction, RICO seeks imprisonment and fine. However, because of the kind of offenders convicted and the scope of the conviction offense, it seeks just sentences that principally incapacitate and only secondarily deter. In sum, rehabilitation is not RICO's main goal. Where rehabilitation occurs fortuitously, proper authorities may modify sentences. In addition to fines, RICO mandates the criminal forfeiture of any asset that the offender used to commit the RICO offense or which the offender gained by it. Finally, RICO authorizes civil remedies by the government for injunctions prohibiting further offenses by offenders, reforming enterprises, and disgorging illicit proceeds of the offense. In addition, RICO authorizes private civil suits to secure remedies for victims. Thus, it is also a theory of remedying (criminally, civilly, and by public and private suits) enterprise criminality.

Use in Fact

At first, the Department of Justice moved slowly to use RICO. Today, it is the prosecutor's tool of choice against sophisticated forms of crime. The Department of Justice is also implementing RICO's civil remedies against corrupt industries and unions. Since 1970, law enforcement has used criminal RICO against organized crime (including Mafia families), political corruption, white-collar crime, violent groups, and terrorist groups.

Studies conclude that RICO is effective in combating sophisticated forms of crime. In 1986, the President's Commission on Organized Crime praised RICO and recommended that states adopt similar legislation. Indeed, 37 states as of 2013 have RICO-type legislation. The General Accounting Office in 1988, in its study of federal organized crime prosecutions, concluded that prior to RICO, attacking an organized criminal group was awkward. Those who designed the system of justice did not have organized crime in mind. RICO now facilitates the prosecution of criminal group members involved in superficially unrelated criminal ventures connected only at well-insulated upper levels of the organization's bureaucracy. Before RICO, the government's efforts were piecemeal, attacking isolated segments of the organization when they engaged in single crimes. When caught, leaders were only penalized for what appeared to be unimportant crimes. The larger meaning of these crimes was lost because the big picture was not presented in a single prosecution. The government now captures and presents the entire picture of the organization's criminal behavior and its members' and leaders' involvement.

The federal government did not bring criminal RICO prosecutions regularly until around 1975. Since 1975, roughly 125 prosecutions occur per year. Thirty-nine percent of RICO prosecutions occur in the organized crime area (not the Mafia alone but also for drugs, gambling, labor racketeering, among other ventures). Forty-eight percent of RICO prosecutions occur for white-collar crime (e.g., government corruption, general fraud in the private sector, securities fraud). Other categories, such as violent groups (e.g., terrorists, White-hate, anti-Semitic), constitute the remaining 13% of RICO prosecutions.

Although few would suggest that RICO is a statute without legal and other controversies, the statute's two-track system of public and private enforcement

(after a slow start) operates largely as Congress originally drafted it. Its impact on organized crime, in particular, on the Mafia, and white-collar crime has been substantial. Similarly, federal officials, as well as private parties, using criminal and civil sanctions, are working toward a more just society.

RACISTS, THEORIES OF

In Western societies, rape tends to be defined as the nonconsensual penetration of the vagina or anus. In the United States, the legal definition of rape at the federal level refers to the penetration of

the vagina or anus with any body part or object or oral penetration by a sex organ of another person. However, at the state level, the source of penetration (e.g., penis, finger, or object), target of penetration (e.g., vagina, anus, or mouth), and gender of the perpetrator or victim can vary across jurisdictions. For example, in Washington State, the source of penetration includes a penis, tongue, finger, or object; in Georgia, it is confined to a male's penis. Similarly, the United Kingdom restricts the legal definition of rape to penile penetration.

Regardless of these variations, research indicates that the occurrence of rape is high. For example, approximately one in six American women has experienced rape or attempted rape during their lifetime. A 2013 report indicated that approximately 85,000 women are victims of rape in England and Wales every year. Given that rape offenses often go unreported to the police, the actual figures may be higher.

In light of these figures, it is crucial to have an accurate theoretical understanding of rape so that professionals are able to detect, assess, and clinically treat/manage perpetrators of rape. This entry discusses rapist typologies, single-factor theories, multifactor theories, theories for sexual offending more generally, and the developmental life course perspective. Since most theoretical work in this area has focused on rape committed by men, this entry will describe theories of male-perpetrated rape against adult females.

Rapist Typologies

One approach to understanding rapists is by categorizing them into subtypes according to a particular characteristic (e.g., motivation). In an early typology, Nicholas Groth and colleagues classified rapists into three subtypes: those motivated by anger, power, or sadistic sexual arousal. Another well-known classification system is the Massachusetts Treatment Center typology by Raymond Knight and Robert Prentky. In it, rapists are categorized into five main subtypes:

1. sexually sadistic (where sexual and aggressive drives are fused)
2. sexually nonsadistic (a sexual preoccupation without the fusion of aggression)
3. pervasively angry (resulting from generalized anger)
4. vindictively angry (resulting from anger directed at women)
5. opportunistic (resulting from general antisociality)

Such typologies are useful for describing characteristics associated with different types of rapists. However, they do not provide a deeper theoretical explanation for the commission of rape.

Single-Factor Theories

Single-factor theories are those that focus on a single aspect that is thought to underpin the cause of rape. One example is *evolutionary theory*, whereby rape is viewed as originating from man's evolutionary history. One view is that rape is the product of a direct adaptation, due to it increasing the reproductive success of ancestral males. Another view is that rape is a by-product of a different direct adaptation that maximized reproductive success (e.g., promiscuous sex). The evolutionary view of rape should not be viewed as deterministic because, according to theorists, rape is only one sexual strategy used by males. However, it does not address other important cultural and psychological factors.

In contrast, *feminist theories* propose that rape is an expression of male patriarchal attitudes and values prominent within society. That is, rape is viewed as a strategy for men to overpower and control women. Thus, instead of an evolutionary adaptation or a distorted psychological characteristic, rape is seen as being the result of the normal cultural-specific socialization of males. Feminist theories have been beneficial in drawing attention to the sociocultural factors that influence rape. However, they have less utility for risk assessors and treatment providers because they do not address the individual psychological factors associated with rapists.

Sociocognitive theories have attempted to address some of the individual factors associated with rape. Specifically, they are based on the view that rapists hold offense-supportive beliefs. These include the belief that women are sex objects, women are dangerous, men are entitled to

whatever they want, the male sex drive is uncontrollable, and the world is a dangerous place. These beliefs affect the way social information is interpreted, which results in distorted cognitive products (e.g., attitudes, decisions). For example, a man who believes women are sex objects (i.e., always receptive to sexual advances) may (mis)interpret that a woman wearing a short skirt is interested in having sex. This misinterpretation may lead the man to conclude that the woman will succumb to and, ultimately, enjoy his sexual advances. Consequently, he decides to continue forcing himself upon her, resulting in a rape offense. This approach opened up many research avenues and has gained support by researchers. However, it only focuses on a single component and so does not provide a full explanation of rape.

Multifactor Theories

Multifactor theories unite numerous single-factor theories in an attempt to provide a more complete understanding of rape. In this section, the most influential multifactor theories of rape are described.

Confluence Model of Sexual Aggression

Neil Malamuth and his colleagues devised one of the first multifactor theories of rape. The theory proposes that rape results from the confluence (or interaction) of a number of risk factors that motivate, disinhibit, and provide the opportunity for sexual aggression. These factors form a constellation of traits and characteristics conceptualized as two pathways. One is the *impersonal sex pathway*, characterized by a preference for promiscuity and sexual conquest. Here, forced sex is used as a strategy to facilitate this behavior. The other is the *hostile masculinity pathway*, which is characterized by the internalization of sociocultural attitudes that promote masculinity and breed hostility toward femininity (e.g., power, dominance, aggressiveness, honor defending, and competitiveness). Thus, men high in hostile masculinity are prone to controlling and being aggressive toward women in both sexual and nonsexual circumstances.

It is theorized that the likelihood of rape is increased by the confluence (interaction) of the two pathways. That is, men high on the risk factors

associated with both pathways are at an increased risk of committing rape. This theory has received a lot of support from researchers and is continually being tested and updated. However, much of the research has been with student and community samples rather than incarcerated rapists.

Quadripartite Model of Sexual Aggression

Gordon Hall and Richard Hirschman proposed that there are four factors that motivate rape. These include sexual arousal (toward coercive sex or toward consensual sex that is so strong it compels the male to seek sex regardless of a woman's consent), cognitive distortions (i.e., the distorted belief that women enjoy sex regardless of the level of coercion), affective dyscontrol (i.e., anger), and personality problems (i.e., antisocial traits). The first three factors are viewed as state dependent while the fourth is conceptualized as being enduring or trait-like. Each individual factor, as well their interaction with each other, increases the likelihood of rape. However, it is theorized that, for each individual, one of the four factors will have a primary influence. It is this *primary motivational precursor* that is responsible for causing an individual to become disinhibited and engage in an actual offense. Also, according to this theory, the four primary precursors can be used to classify rapists into four subtypes. Thus, a strength of this theory is that it takes into account the different types of rapists. However, unlike other theories, the quadripartite model has received little testing or support from researchers.

Unified Theory of Sexual Coercion

In their unified theory, Raymond Knight and Judith Sims-Knight propose that early childhood abuse (physical/verbal and sexual) interacts with three overarching factors that can lead to rape. These factors include

1. callous/unemotional traits (e.g., arrogant, deceitful personality, and emotional detachment),
2. antisocial behavior/aggression (e.g., impulsive acting out), and
3. sexual fantasy (i.e., sexual preoccupation/compulsivity and hypersexuality).

More specifically, the theory describes three pathways to rape. In the first pathway, early physical or verbal abuse leads to callousness and unemotionality, which disinhibits the sexual drive/fantasies. This leads to the disinhibition of aggressive sexual fantasies, which leads to rape. In the second pathway, sexual abuse directly disinhibits sexual drive/fantasies, which leads to rape via aggressive sexual fantasies. Finally, in the third pathway, physical/verbal abuse and callous/unemotionality both contribute to the development of antisocial and aggressive behavior that, in turn, leads to rape both directly and indirectly (via aggressive sexual fantasies).

The strength of this theory is that it combines many factors that are statistically associated with rape. It has also been tested (and supported) using adult and juvenile rapists as well as community males. However, it is still open to further development, such as by including other factors that are identified by further research.

Theories of Sexual Offending

In addition to theories designed to specifically explain rape, other theorists have proposed multi-factor theories for sexual offending more generally. An example is the integrated theory of sexual offending developed by Tony Ward and Anthony Beech. According to this theory, certain biological factors (e.g., genetic predisposition, brain development) and environmental factors (e.g., sociocultural and personal circumstances) can lead to changes in the neuropsychological functioning responsible for an individual's emotions, memory, and motivation. These changes result in the development of risk factors (e.g., emotional dysregulation, deviant sexual arousal, offense-supportive beliefs), which increase the likelihood of sexual offending behavior.

This theory takes into account the multitude of causal factors related to sexual offending, thereby providing a general explanatory framework that can be applied to rape. However, due to its generality, the specific factors associated with rape are not discussed in any depth, which may reduce its ability to fully explain rape per se.

Future Directions

Since the early 2000s, a different approach to understanding has received increased attention.

This approach adopts a developmental life course perspective. Longitudinal research has demonstrated that rape is typically characterized by high levels of discontinuity. In other words, it is more often a short-lived and opportunistic form of offending. Therefore, rather than concentrating primarily on the onset of rape, life course theorists focus more on the development of rape. This involves identifying and explaining the factors that influence both the commission of rape (risk factors) and the desistance from rape (protective factors) at different developmental stages of an individual's life. Life course theorists argue that this approach will help to explain the onset, maintenance, and termination of rape more fully, which will be useful for professionals who work with rapists (e.g., clinicians, policy makers, police officers).

In summary, many scholars from various disciplines have contributed to a comprehensive theoretical understanding of rape. As described earlier, a number of factors have been identified as playing an important role in the onset and continuation of rape. These include biological/evolutionary predispositions, the sociocultural context, the mindset of the individual (influenced by early, often abusive, experiences, and prominent societal attitudes) that leads to faulty processing of interpersonal information, affective problems that disinhibit aggressive sexual and nonsexual behavior (e.g., anger, hostility, callousness), sex-related factors (e.g., sex drive, fantasies), and personality-related issues (e.g., antisocial traits).

Although existing insights have brought the forensic field closer to understanding rapists and the different subtypes, rape is a complex phenomenon and there is still a lot more to understand and explain. Fortunately, as technology and research methods continue to advance, the ability to uncover new insights increases. As such, the theoretical understanding of rape will continue to advance, which will enable forensic professionals to better assess and treat rapists as well as potentially prevent rape from ever occurring.

RAPISTS, TYPOLOGIES OF

Sexual offenders are a heterogeneous group, in that there is a no single profile to encompass the entire population. Sexual offenders differ in regard to personal characteristics (e.g., demographics, personality traits, attitudes and beliefs, interpersonal skills) as well as the features of their crimes (e.g., time and place, age and gender of the victim, degree of planning, amount of force used). The term *rapist* is used to describe one type of sex offender. This term is reserved for individuals who commit the act of rape, which the Federal Bureau of Investigation has defined as nonconsensual vaginal or anal penetration by any body part or object or oral penetration by a sex organ.

Even within the category of rapists, there are high degrees of variability between offenders. In

an effort to gain a better understanding of rapists, there have been several attempts to classify rapists based on the offender's traits and behavioral patterns. These systems of classification are often referred to as *typologies* that aim to organize a variety of observations and measurement which can later be used for research or clinical purposes. Although there have been various propositions about the typologies of rapists, this entry outlines the most commonly cited. Much of the literature has focused on male offenders; thus, the typologies outlined below mainly describe rape committed by males against adult female victims.

Groth's Rapist Typologies

In 1979, A. Nicholas Groth Aloysius was one of the first to develop a classification system for rapists based on the underlying motivations of the offender. He proposed that there were three major categories of rapes: (1) anger rape, (2) power rape, and (3) sadistic rape. First, anger rape describes instances where the offender uses excessive amounts of force against the victim, often engaging them in demeaning or humiliating sexual acts. For these offenders, rape is a deliberate act that stems from anger directed at females, and this rage is exhibited both physically and verbally during the sexual act. Second, in the instance of power rape, the offender's goal is to establish power and control over the victim. The degree of force used will depend on the level of submission that the victim exhibits. Penetration of the victim is used to assert authority and dominance rather than solely for sexual gratification. Third, in sadistic rape scenarios, the offense involves a combination of sexual and aggressive characteristics. The sadistic rapist's sexual arousal stems from the victim's suffering and distress. Therefore, these cases may often involve torture or bondage, which results in high levels of physical injury to the victim. Groth's research has revealed that 55% of offenders were power rapists, 40% were anger rapists, and 5% were sadistic rapists.

Massachusetts Treatment Center (MTC) Classification System

Since the publication of Groth's typologies, others have sought to expand upon his findings. Most

notably, the MTC system of classification has been deemed the most rigorously tested. The MTC classification system is based on motivational and behavioral components to the sexual offense. The MTC rapist typology is currently in its fourth version, following several revisions throughout the years. Below, the original MTC typology is described, followed by a description of important revisions made in subsequent versions.

Original MTC Typology

In the original MTC typology, rapists were classified into four major categories: (1) displaced aggression, (2) compensatory, (3) sexual aggressive, and (4) impulsive. In the instance of displaced aggression rape, the primary motivation is aggressive and the assaults will be violent. These assaults are accompanied by little to no sexual arousal. Rather, the aim is to humiliate and degrade the victim. Second, compensatory rapists assault a victim due to intense sexual arousal in relation to environmental stimuli. These rapes are not typically aggressive; rather, the offender is motivated to prove his sexual adequacy. Compensatory rapists may show poor interpersonal skills and do not typically show other antisocial tendencies. Third, sexual aggressive rapists, similar to that of Groth's sadistic rapists, demonstrate both aggressive and sexual components to the crime. Two features must be present: (1) the level of force used is excessive compared to what is needed to gain the victim's compliance and (2) there is clear evidence that the violence is sexually arousing to the individual. The sexual aggressive rapist may view the victim's resistance as part of a game and believe that women want to be controlled by men. Fourth, impulsive rapists commit spontaneous acts of rape if the situation arises. These types of rapes are generally found in the context of other offenses (e.g., robbery or burglary). Two features must be present: (1) indifference toward the welfare of the victim and (2) only the level of force necessary to gain the compliance of the victim is used.

MTC's Third Revision

According to Raymond A. Knight and Robert A. Prentky's 1990 publication, the MTC's third revision was developed to identify four major

types of rapists, similar to those proposed in the first version of the MTC. The developers found that there were four primary motivations for committing rape: (1) opportunity, (2) pervasive anger, (3) sexual gratification, and (4) vindictiveness. Within these four overarching motivations, nine subtypes were identified.

First, opportunistic rapists (Types 1 and 2) largely mirror impulsive rapists from the original MTC, in that the acts are committed on impulse when the situation arises. These types of offenders can further be divided in terms of high social competence (Type 1), who first display impulsive sexual acts in adulthood, and low social competence (Type 2), who first show these tendencies in adolescence. Second, pervasive anger rapists (Type 3) show anger in all domains of their lives and toward all people, not just women. They tend to have long histories of antisocial behavior and show high levels of violence toward victims. Third, the sexual gratification category (Types 4, 5, 6, and 7) are divided into sadistic (Types 4 and 5) and nonsadistic (Types 6 and 7) subtypes. Within the sadistic type, the offender's fantasies are either overtly expressed (Type 4) or are muted (Type 5). Nonsadistic types are split on the basis of low (Type 6) or high (Type 7) social competence. Fourth, the vindictive category (Types 8 and 9) includes offenders who show anger exclusively toward females, similar to the displaced aggression type in the original MTC. These offenders can be further divided into those offenders who are low (Type 8) and high (Type 9) in social competence.

MTC's Fourth Version

In the fourth revision, all of the categories for the MTC's third revision were retained except for the muted sadistic rapist (Type 5). Additionally, in a 2010 publication, Knight discussed the importance of considering core personality traits that lead a person to sexually offend. These traits include (a) callous unemotionality, (b) antisociality/impulsivity, and (c) hypersexuality/sexualization. Knight suggested these traits can be found on a dimension rather than strictly in categories. Although the newest MTC development is intriguing, much more research is needed to support this model.

Uses and Limitations

Overall, typologies are beneficial in illustrating the diversity of motivations and behaviors for rape. These classification systems can lead to a better understanding of the etiology of rape. Further, typologies can aid crime-scene investigators in identifying the type of offender who committed the rape. They can also help inform clinicians regarding treatment decisions and determinations of risk of recidivism.

There are some limitations that should be noted. First, not all sexual offenders will fit neatly into the categories proposed. This has led some to propose a dimensional approach that may be more inclusive and accurate. Second, the typologies do not account for rapists who engage in crossover offending by assaulting victims of varying ages. Third, an individual's motivations and behaviors may change over time, which can lead to shifts between categories. These limitations shed light on the importance of continued research on the typologies of rapists.

RECIDIVISM

Recidivism originates from the Latin phrase that means *to fall back*. It is most often used in criminal justice to refer to a return to criminal behavior, but it may also refer to a return to other behaviors such as substance abuse. Conceptually, recidivism is defined by Michael Maltz as a reversion to criminal behavior after punishment. This means that for one to recidivate, a punishment must first occur. Recidivism may also refer to reoffending, multiple offending, or habitual offending. Although the conceptual definition of recidivism is clear, what criminal behavior may be defined as recidivism often varies. Besides rearrest, recidivism can also mean reincarceration (i.e., the return to custody of an individual who has been previously incarcerated) or reconviction (i.e., a subsequent conviction of an individual who has been previously convicted). Each measure of recidivism is defined by the level of involvement in the criminal justice system that represents correctional failure. For example, rearrest would represent failure due to any formal involvement with the criminal justice system. In contrast, recidivism measured by reincarceration or reconviction represents involvement in multiple areas of the criminal justice system: law enforcement, the courts, and correctional system. Each measure satisfies different purposes for examining post-punishment reversion to criminal behavior. This entry provides an overview of recidivism, including how it is measured and how it is related to punishment, the offender, and the criminal justice system.

Recidivism Measurement

Recidivism is most commonly measured as a rate. This is a ratio of the number of individuals who have received a punishment and reverted to criminal behavior within a certain period of time to the number of individuals who have received that punishment. Recidivism is used as a marker of a failed (i.e., ineffective) punishment. How high or low a recidivism rate may be for a certain punishment is often an indicator of whether that punishment is considered to be meeting its goal to deter individuals from future offending. Recidivism is

one of the primary and most commonly used measures of the effectiveness of correctional programs.

Recidivism can be measured by different types of records, but official crime records are used most often. Alternative forms of crime reporting, such as self-report or victimization, may be used to measure recidivism, but most often, offenses detected by law enforcement are markers of subsequent criminal behavior. This means that recidivism measures often neglect subsequent criminal behavior unknown to law enforcement. Since not all criminal behavior is known to law enforcement, recidivism rates calculated with official data are limited in their representation of all subsequent criminal behavior.

Recidivism and Punishment

The overarching goal of punishment is to deter an individual from committing a certain act. Correctional goals are aimed at deterring individuals from committing further criminal acts under the assumption that offenders are in need of correction to change their behavior. For this reason, recidivism is often used to define how effective or ineffective a corrective approach is to meeting this overarching goal. Recidivism rates can be used to evaluate any correctional program. The lower the recidivism rate, the more effective a correctional program is thought to be at meeting its goal. Recidivism rates are not the only measure of program effectiveness. For example, a recidivism rate of a rehabilitative correctional program will only provide insight as to whether participants did or did not reoffend, but not whether these individuals were rehabilitated. Alternative measures of correctional program effectiveness can include measures of offender prosocial success, such as obtaining employment, or rehabilitation, such as refraining from substance abuse.

Recidivism measures can vary according to characteristics of the punishment or the subsequent criminal behavior. Different types of punishment have different goals, making some measures of recidivism more useful for evaluating the effectiveness of certain punishments than others. For example, rearrest for the same offense is useful for evaluating punishment that seeks to correct specialized offending. However, when

examining general reoffending, rearrest for the same offense does not provide enough information to calculate an accurate recidivism rate. Rearrest for the same offense is a more restrictive measure of recidivism in its representation of a program's effectiveness than one that defines recidivism as any subsequent criminal behavior after a certain punishment.

There are also different recidivism measures according to the type of punishment under evaluation and when recidivism can actually occur. Certain punishments require the measurement of whether a criminal behavior has occurred at the inception of the punishment or, alternatively, at the completion of the punishment. For example, punishment with the goal of incapacitation seeks to eliminate any opportunity to commit a subsequent criminal behavior while the punishment is being imposed. A useful recidivism measure would begin counting subsequent criminal behavior that occurs while the punishment is being imposed. Alternatively, punishment with the goal of rehabilitation seeks to reform offenders by the completion of the punishment imposition. A useful recidivism measure of this correctional program's effectiveness would count subsequent criminal behavior that has occurred only after the program has been completed.

Different types of criminal events can also be used to define recidivism. These events include arrest, prosecution, conviction, or violation of the conditions of one's community corrections sentence. Some of these events may also provide a more restrictive definition of recidivism than others. The events that provide a more restrictive definition of recidivism (e.g., conviction is more restrictive than arrest) lead to fewer subsequent criminal behaviors being labeled as recidivism. For example, if a number of arrest events do not lead to a conviction, those who are arrested and not convicted would ultimately not be defined as reoffending. The most commonly used definitions of recidivism are arrest and conviction.

Recidivism and the Offender

Recidivism is also a useful measure for identifying common characteristics of offenders. Measures of recidivism provide insight into how frequently offenders reoffend, how long they are likely to

take to reoffend, and what characteristics are most prevalent among offenders who may or may not reoffend. The rate and frequency of the occurrence of recidivism are often used to understand how often offenders engage in subsequent criminal behavior. This is useful for understanding both the probability and how likely multiple offending is to occur.

The severity of subsequent criminal behavior is also relevant to the effectiveness of a correctional punishment. Punishment is considered more effective for offenders who revert to less serious criminal behavior. Comparatively, subsequent offending that involves an escalation in the severity of criminal behavior represents a greater degree of recidivism. A lower degree of recidivism may be considered successful when the goal of punishment is to restrictively deter subsequent offending.

Measuring the amount of time between receiving punishment and a subsequent criminal behavior provides insight into how long the effect of the punishment on reoffending may last. Certain offenders may take a longer or shorter amount of time to reoffend after receiving a punishment. Those offenders who take a shorter amount of time to revert to subsequent criminal behavior are thought to be higher risk offenders. A punishment's effectiveness may also be evaluated by the amount of time it takes for an offender to recidivate. Punishments that result in a longer amount of time to recidivate compared to a shorter amount of time are viewed as more effective at meeting their correctional goals. Punishments that have no significant influence on how often recidivism occurs may be considered effective if they are still found to delay the time an offender takes to revert to criminal behavior.

Recidivism measures are useful for identifying characteristics among offenders who reoffend. The characteristics often found among offenders who recidivate are considered to be predictors of recidivism. There have been a variety of predictors identified in studies of recidivism, including age, gender, criminal history, offender family factors, and criminal peers. These predictors are used by criminal justice corrective agencies as risk factors for identifying offenders who are more likely to revert to subsequent criminal behavior after receiving a punishment. Some of these predictors of recidivism have received more support in the study

of recidivism than others. The reliability of these characteristics in predicting recidivism does vary by characteristic, resulting in the validity of some of these to be debated. These characteristics that identify higher risk offenders are most often used to inform criminal justice practitioners about the most effective punishment for a certain offender at meeting the goal of reducing recidivism.

The variation in how recidivism is measured makes comparing predictors of recidivism across studies problematic. However, there is strong evidence that younger offenders are more likely to recidivate than older offenders. One of the earliest recidivism studies by Adolphe Quetelet in 1833 found that criminal behavior peaks during the teenage years. There is also strong evidence that criminal history may also predict the likelihood of reoffending. Offenders who have at least one prior criminal conviction are more likely to reoffend than first-time offenders.

Risk of recidivism is commonly evaluated using risk assessment tools. These are surveys that determine an offender's risk of recidivism by measuring the offender's characteristics that predict recidivism. The risk score from this assessment is used to inform corrective approaches that will be the most effective at reducing recidivism, individually, for each offender. There are a variety of risk assessment tools that measure different types of recidivism. Certain tools only measure risk of certain types of recidivism, while other risk assessment tools measure any predictors of general recidivism.

Recidivism and Criminal Justice Policy

Recidivism rates are used by many different parts of the criminal justice system. In the United States, the U.S. Department of Justice reports recidivism rates across states and of the nation. This reporting informs policy makers and practitioners about the effects of different corrective approaches. Comparison of nationwide recidivism rates provides insight into patterns in offending as well as the effectiveness of corrective approaches in different countries and legal systems.

Evaluation of program effectiveness using recidivism commonly addresses the question of what correctional approach actually works. The effectiveness of a tough punishment approach at

reducing recidivism has been largely debated. One of the reasons attributed to this inconsistent evidence of punishment's influence on recidivism is due to the variation in how recidivism is measured. Comparison across recidivism evaluation studies is limited because they use different recidivism measures, making most estimates of a punishment's effectiveness incomparable. For example, the effects of punishment found in a recidivism study measuring recidivism as reconviction examine a reversion to subsequent criminal behavior as found by the courts. Alternatively, the effects of punishment as reported in a recidivism study measuring recidivism as reincarceration represent a reversion to subsequent criminal behavior as well as the probability of receiving an incarceration sentence. A punishment's effect on both of these outcomes is likely different and comparing it would produce an inaccurate conclusion.

One approach to reducing recidivism rates has been to increase the length of sentence of incarcerated, habitual offenders. Sentence enhancements for those who have prior convictions for either the same or different offenses are a common corrective approach to reducing recidivism. The effectiveness of this approach at actually reducing recidivism has also been largely debated. Longer sentences for habitual offenders do provide a greater opportunity for incapacitation and for offender treatment that is likely to reduce recidivism. However, such practices have also been found to result in the mass incarceration of non-violent offenders putting a large strain on resources within the criminal justice system.

Final Thoughts

Recidivism is an important concept used by the criminal justice system. It is useful to evaluate the effectiveness of corrective programs and identify offenders likely to reoffend. A variety of recidivism measures are employed in the criminal justice system and inform decisions by both policy makers and practitioners.

REENTRY

Reentry in a criminal justice context describes the transition from being incarcerated in a jail or prison to returning to life in the community. For over 30 years, the United States experienced an unprecedented increase in the numbers of individuals admitted to and subsequently released from prisons. According to data maintained by the Bureau of Justice Statistics, the number of prisoners released from federal and state prisons increased more than fivefold between 1978 and 2008 (from 142,033 to 734,144). In 2009, the annual number of reentering prisoners declined for the first time in decades—a pattern that has continued through 2012. Even with the recent decline in releases, more than 600,000 prisoners are released each year from state and federal prisons, with 626,024 individuals released in 2016. Moreover, these figures do not include the substantially larger number of individuals released each year from local jails. According to the Bureau of Justice Statistics, local jails admitted nearly 12 million persons in 2013 when the average daily jail population was 731,470. The average jail population was approximately the same in 2016—731,300—but admissions declined dramatically during 2016 to 10,600, suggesting that as admissions declined, the length of stay must have increased. Successful reentry poses a difficult challenge for many offenders, as research from the Bureau of Justice Statistics suggests that more

than half of reentering prisoners are reincarcerated within 5 years. Given that most prisoners reenter communities and that there are high expected recidivism rates, it is important to understand the process of transitioning back to the community and to identify ways to reduce the likelihood of criminal activity after release. This entry reviews the needs of reentering individuals, the types of programs and services directed at the reentering population, and the role that community context plays in successful reentry.

Needs of Reentering Individuals

Prisoners transitioning from incarceration to the community face numerous impediments to success, including low educational attainment, limited job experience and training, substance use disorders, strained relationships with family members and friends, and the stigma associated with a criminal record. Although recidivism may be the most common metric used to measure successful reentry, there are numerous intermediate outcomes that reflect successful navigation of immediate needs that may impact an individual's ability to desist from criminal behavior.

Some of the most common self-reported needs of reentering inmates include basic necessities such as transportation, housing, food, clothing, health insurance and medical care, identification documents (e.g., photo ID card, Social Security card), and financial assistance. If these necessities are not met, former inmates may feel their only option is to resort to engaging in criminal activities.

In addition to basic needs, many inmates need education, vocational training, and assistance finding a job. If a legal source of income is not attained following release, reentering individuals may seek out illegal activities for money to support themselves and their families. Their ability to gain employment and become functional members of society may also be hindered by drug addiction and physical and mental health problems. Without adequate treatment for these conditions, they may be unable to successfully reintegrate. Furthermore, reentering individuals may need to mend personal relationships with family and friends, which may have been damaged due to their criminal behavior or incarceration. Emotional and

instrumental support provided by loved ones can ease the transition from prison to the community.

In short, although desistance from crime is often seen as the top priority of reentry programming, reintegrating offenders into the community may first require building some of the basic foundations needed to become (and stay) a productive member of society. Without this strong foundation, desistance from crime may be challenging.

Reentering individuals do not all face the same set of needs and challenges; there is evidence that reentry needs vary greatly by gender. For example, men and women enter the criminal justice system with notably different circumstances and needs that may be further compounded upon release. Male offenders are more likely to participate in violent crimes than females, who are more likely to participate in property and drug offenses. Female offenders are more likely than their male counterparts to have been victims of sexual and physical abuse. Moreover, research indicates that female offenders are more likely than male offenders to have chronic physical and mental health conditions and to have comorbid mental health and substance abuse issues. When women are released from prison, they often have more difficulty than their male counterparts accessing substance abuse and mental health treatment, have unresolved issues related to prior victimization, and have difficulty securing employment. Furthermore, although these circumstances may mean that women have a greater need to rely on family members for financial support to avoid homelessness, research suggests that women may actually have less support from family than comparably situated men. Female inmates are also more likely to be parents and to have more children than reentering males. These differences highlight the need for gender-responsive programming and services to ensure that the unique needs of reentering men and women are met.

Reentry Programs and Services

Given the large number of individuals reentering society from jails and prisons each year, it is important to identify programs and services that can assist in removing obstacles to successful reentry. Since the early 2000s, federal efforts have focused on improving a variety of outcomes

among reentering individuals through the development and implementation of services and programs for prisoners. For example, starting in 2002, the Serious and Violent Offender Reentry Initiative (SVORI) provided funds to help states address criminal justice, employment, health, and housing outcomes. This unprecedented national response to the growing challenge of reentry involved funding agencies to enhance or establish reentry programs and services. SVORI grantees included 69 state and local corrections and juvenile justice agencies, each of which received \$500,000–\$2,000,000 over 3 years. The funding was intended to create a continuum of services for returning prisoners in state prisons and juvenile facilities that would begin during incarceration and continue after release as former inmates reintegrated into the community. Programs were locally designed and included a broad range of services and programs (e.g., needs assessments, reentry planning, drug treatment, mental health treatment, educational/vocational programs) to address the complex issues that reentering prisoners face.

After SVORI ended, the Second Chance Act of 2007 was enacted with similar goals to help state and local agencies address the challenges of prisoner reentry across multiple domains (i.e., housing, education, employment, family relationships, substance abuse treatment, mental health treatment, and cognitive behavioral therapy). Between 2009 and 2015, more than \$475,000,000 had been authorized under the Second Chance Act to provide training and technical assistance to government agencies and community-based organizations to provide reentry services to those releasing from jails, prisons, and juvenile confinement. As of March 31, 2015, the Bureau of Justice Assistance had made more than 600 awards that have served over 100,000 participants. The funded programs include reentry courts, adult mentoring, technology careers, family-based substance abuse treatment, treatment targeting adults with co-occurring mental health and substance abuse disorders, an adult offender reentry demonstration, and recidivism reduction strategic planning.

In addition to these large federal initiatives, there are numerous other reentry programs funded by state and local agencies. A broad range of services may be offered to assist with the transition

back to the community. Reentry services may provide resources to meet basic needs, educational and vocational assistance, treatment for drug abuse or mental illness, or other identified needs. Some programs provide multiple services while others focus on specific issues. Programs may provide services in prisons or jails prior to release and/or in the community both for reentering inmates who are on probation or parole and those who were released without a sentence to supervision. Services delivered in prison prior to release often focus on preparing the inmate for release through teaching skills and modifying attitudes and behavior. Postrelease services help ensure that progress made while incarcerated persists during the transition to the community. Services may be provided by correctional, public health agencies, or other government agencies; faith-based organizations; and/or other community-based organizations and service providers. Some programs may be designed to be completed in a few weeks, whereas others may serve clients for years. In short, there is not one way to provide reentry support, and the availability of programs and services varies greatly over time and by location.

There is a growing body of research on *what works* for reentering juvenile and adult offenders. A multisite evaluation of SVORI found that program participation was associated with moderately better outcomes in housing, employment, and drug use in the first 15 months after release. Analysis of long-term recidivism among offenders in the SVORI data suggested that receipt of more services associated with individual needs (i.e., mental health and substance use treatment, assistance working on personal relationships, training on changing criminal attitudes, anger management, and education) was more likely to be beneficial than receipt of more practical services (i.e., case management, needs assessment, reentry planning and programming, life skills, and employment services). These evaluation findings are consistent with growing evidence that cognitive behavioral therapy and services targeting individual criminogenic risk and needs and focusing on individual-level change can reduce recidivism. Services focused on practical needs, such as life skills and reentry preparation, have been found to be among the least effective services. These human service-oriented programs, however,

are more promising than deterrent approaches that rely solely on intensive surveillance. For example, there is evidence that intensive supervision probation/parole is not effective on its own but, paired with a strong treatment component, can reduce recidivism. There is also some qualitative evidence that successful desistance from criminal activity and drug use begins with the realization by an individual that change is needed to have a desirable future. To address this realization, the individual then pursues an identity transformation (e.g., "I will no longer be someone who takes drugs. I will be someone who takes care of my children") and, in turn, begins the process of no longer engaging in crime and drugs.

These findings on *what works* are more consistent with theories of desistance positing that individuals must transform themselves into nonoffenders than other more structural perspectives that address correlates of crime such as drug use and inadequate education and training. Early research on criminal desistance by Robert Sampson and John Laub emphasized the impact of structural and social factors, such as employment and marriage, on changes in criminal behavior over the life course. Indeed, there is empirical evidence to support the suggestion that stable employment and a good marriage are associated with desistance. It is important to note that it was argued that the quality of and commitment to these life events is what impacts desistance, not merely their occurrence. However, securing a quality marriage and stable employment are, at least in part, events of chance. This suggests that other internal changes or cognitive transformation were not viewed as necessary prerequisites.

Peggy Giordano, Stephen Cernkovich, and Jennifer Rudolph stressed that offenders must engage in much *up-front* work before structural change, such as finding a job or a partner, is a viable option. Raymond Paternoster and Shawn Bushway put forth an identity theory of criminal desistance that is grounded in the idea that identity is multifaceted, such that one may have a *working self* and a *possible self*; the former is oriented toward the present and the latter toward the future. They suggest, in summary, that individuals are committed to the working self until its costs outweigh its benefits; gradual change in identity may occur as one experiences failure or

dissatisfaction, anticipates its continuance in the future, and links this discontent to the working (criminal) identity. Once the criminal identity is weakened, identity change is possible.

The Role of the Community in Successful Reentry

The collateral consequences of reentry go beyond those experienced by the individual. Indeed, community instability associated with a large number of removed and reentering individuals may impede efforts at successful reentry. Some research suggests that the neighborhood to which an offender returns may impact recidivism, with those returning to areas of concentrated disadvantage and poverty faring worse than others. The aggregated social consequences occur because of the spatial clustering of incarceration and reentry. Prison admissions and releases are not evenly distributed across cities or states. Indeed, research has indicated that the incarceration and reentry phenomenon is spatially uneven such that it is clustered in poor, urban, disadvantaged communities that are characterized by racial segregation, unemployment, and poverty. The extent of spatial clustering of individuals who enter and leave U.S. jails and prisons helps perpetuate a cycle that creates a criminogenic environment hindering reentry and fostering future incarceration for younger generations.

The cycling of individuals in and out of jail and prison generates residential instability, a key contributor to social disorganization. Criminologists have long recognized that neighborhoods that are more stable and socially organized are better able to achieve shared goals, such as public safety. The residential instability resulting from high concentration of prison admissions/releases in a neighborhood also disrupts social networks, destabilizes the labor market, and reduces informal social control, collective efficacy, and social capital. In short, clustered prison admissions and releases act as a feedback loop to undermine the structures and social organizations of communities, yielding more criminogenic environments for returning prisoners and hindering their chances at successful reentry. This underscores the importance of considering community characteristics in developing and implementing reentry programming. Yet reentry programs have focused

almost exclusively on services and programs provided to the returning offender. Given the spatial clustering of crime, incarceration, and community disadvantage, services at the individual level may not be sufficient.

REENTRY, BEST PRACTICES FOR

In the United States, an increase of crime in the 1980s and the *War on Drugs* (which began in the 1970s) led to the passage of criminal laws that strengthened punitive measures for violent and drug crimes. Those laws have led to drastic increases in incarceration. As a result, the number of prisoners released from prison has also increased. This process of leaving prison after a period of incarceration is known as *prisoner reentry*.

With a growing number of prisoners being released, communities are faced with the challenge of assisting returning prisoners with a range of needs. Preparing returning prisoners for release, identifying needs and services, and supervising them while in the community are all part of the reentry process. The aim of prisoner reentry is to be able to provide effective services and support so that returning prisoners can successfully reintegrate back into society. Part of reentry success involves preventing reoffending and subsequently a return to prison. Some of the reentry challenges and best practices to help individuals succeed after prison are discussed in this entry.

The Growth of Prisoner Reentry

Prison populations have seen drastic growth over the advent of the crime reduction policies and stricter criminal laws. Within the span from the 1970s to the early 1990s, prison populations spiked more than fivefold, which has also contributed to drastic increases in the numbers of prisoner releases.

The total number of people incarcerated in state prisons nationwide has been estimated to be approximately 1.6 million. Each year over 600,000 prisoners are released. The increase in the numbers being released is not strictly attributable to the increased number of those being sentenced to prison. Changes in sentencing policy nationwide also played a major part. A shift away from indeterminate sentencing (i.e., judicial discretion in sentencing decisions) to a determinate model (i.e., requirement for specific prison terms for certain felonies) impacted the number of people who were sent to prison. Even though the changes in

sentencing policies meant more people were being sent to prison, and for longer periods of time, 95% of people who go to prison eventually return to the community.

Reentry Barriers

Prisoner reentry is an important issue because of the significance of being able to have prisoners successfully reintegrate into society, without recidivating and returning to prison. Recidivism is often defined as either an arrest for a new crime, a new conviction, and/or a new incarceration. The Bureau of Justice Statistics estimates that about 68% of prisoners released from state prison will be arrested for a new offense within 3 years of release.

Providing reentry services and programs can reduce recidivism and assist former prisoners to be able to make the transition from prison to society. Due to their status as convicts, former prisoners face substantial challenges in their quest to reintegrate into society. Four key challenges that they face are employability, housing, physical and mental health issues, and substance abuse issues.

Employability is a hurdle that former prisoners face due to low educational attainment, unemployment history, or lack of work experience. The stigma associated with having a criminal record also impacts their ability to secure work. Housing is also challenging to secure and is typically the most immediate need upon release from prison. Housing barriers often result from a lack of affordable housing, laws preventing former prisoners from living in certain public housing buildings, and in some cases, relationship conflicts preventing an individual from living with family or friends. Physical and mental health issues, along with substance abuse issues, are additional barriers. The prison population has a higher rate of physical health, mental health, and substance abuse issues than the general population, which makes treatment services a crucial need for this population. Those who receive treatment in correctional facilities, and continue to do so after release, are more likely to be successful in integration than those who do not; however, not everyone with a need for treatment receives it while incarcerated. Many of the barriers highlighted here may lead someone to recidivate if these issues

are not addressed while incarcerated and/or in the community once released.

Best Practices Defined

Best practices for reentry are strategies, principles, and programs that have been identified through scientific research as effective at reducing recidivism. The term *best practice* is sometimes referred to as *what works*. The knowledge on *what works* is limited to programs and practices that have been evaluated. Programs and practices identified as effective are often evaluated multiple times or evaluated using rigorous research methods. Some programs and practices that have been evaluated only once, or with low rigor, may be considered *promising*—meaning that there is some evidence that they are effective, but more research is needed. The National Institute of Justice, Office of Justice Programs developed a website called *Crimesolutions.gov* to assist criminal justice practitioners with a searchable list of effective, promising, and noneffective programs and practices.

Key Best Practices for Reentry

There are certain effective practices that have been shown to make the reentry process successful. The core practices, or principles, are known as the *Risk-Need-Responsivity model*. Developed by several Canadian psychologists (Don Andrews, James Bonta, and Paul Gendreau), this model has been the leading strategy for preventing recidivism since the mid-1980s. The principles of the model have been evaluated numerous times and are considered effective at reducing levels of recidivism for offenders who participate in programs that incorporate these principles.

The first component—the *risk principle*—is designed to identify the level of risk of an offender. This is traditionally done through the use of an assessment tool that predicts criminal behavior. One of the most common risk assessment tools is the Level of Service Inventory–Revised. The higher an individual scores on an assessment tool, the more likely he or she will reoffend; therefore, the individual is considered high risk. Individuals scoring moderate- to high-risk levels should be targeted for treatment services because they are the most in need of assistance.

The *need principle* is designed to target multiple criminogenic needs. Criminogenic needs are also termed *dynamic risk factors* because they are characteristics that change. For example, employment status, substance use, and education level are criminogenic needs that may change when the appropriate services or treatment are provided. When released from prison, many offenders have multiple criminogenic needs that require treatment services. If needs are not addressed, recidivism is likely to occur.

The *responsivity principle* involves designing treatment programs based on social learning and cognitive behavioral approaches. Cognitive behavioral treatment is used to help offenders identify problematic thinking patterns and develop ways to change behavior by altering the thought process. The responsivity principle also involves adapting treatment programs to fit individual client characteristics such as age, gender, race/ethnicity, and learning styles.

There are other elements of the prisoner reentry process that are considered best practices. These include aftercare, nonpunitive approaches, vocational and educational programs, professional staff, motivational interviewing, and the use of graduated sanctions.

Aftercare (or continuity of care) involves continuing treatment in the community after treatment already began inside the prison setting. This is most common in drug treatment programs. Continuing treatment in the community prevents a break in services and is considered a necessary component to prevent relapse. Two effective programs that follow this practice are Delaware's KEY/CREST therapeutic community program and Amity In-Prison Therapeutic Community Program. Both programs provide intensive drug treatment in prison and include an aftercare program in the community. The programs start during the last year of incarceration and continue with 6 months of drug treatment in the community in addition to other transitional services (e.g., employment, housing).

Programs and interventions should be *nonpunitive* or control oriented; instead, they should be designed to include skill development, family treatment, and cognitive behavioral treatment. Having a range of programs that address many criminogenic needs is considered effective.

Providing services in the community when possible is another best practice. *Community settings* are considered to be more therapeutic and less punitive than institutional environments.

Vocational and educational programs provided in prison, and in the community, are another best practice. Individuals who have the opportunity to participate in skills and education training are less likely to recidivate than those who do not participate in such programs.

Best practices also include hiring professional staff and providing them with the tools to work effectively with the returning prison population. Certain *staff characteristics* are needed to develop meaningful client relationships. Best practices in hiring staff include targeting staff with strong relationship-building skills, caring and empathetic personality, good problem-solving skills, and ability to display positive role modeling and reinforcement. Training staff in *motivational interviewing* techniques is also a best practice. Motivational interviewing is used to guide offenders to change behavior through the use of directive, goal-oriented counseling techniques. This approach is designed to identify clients' readiness to change behavior and commitment to participating in services. Staff working in reentry programs, and parole/probation officers, are often trained to use motivational interviewing during meetings or counseling sessions with offenders.

Successful reentry also involves providing parole and probation officers with tools to be successful. Motivational interviewing is one of these approaches; however, there are other strategies as well. One such strategy is the use of *graduated sanctions*—that is, having a range of options to respond to offender behavior. Rewarding positive behavior through verbal recognition, certificates of success, or decreasing level of supervision is a way to encourage offenders to continue on a path of success. Punishing negative behavior through increasing supervision level, referrals to more intensive treatment, or returning the offender to jail or prison is a strategy to discourage behavior that violates conditions of supervision. This graduated sanction practice provides officers with more tools to respond to client behavior rather than relying on incarceration as a sole option.

Although there are many best practices for reentry, more research is needed to determine

whether other strategies may also be effective at reducing recidivism.

REHABILITATION

The word *rehabilitation* is used in a number of contexts and has several different but interrelated meanings. In health services, it denotes a process of being restored to normal functioning after an injury or period of illness. In addiction services, it entails being empowered to escape the destructive use of a substance and regain control over one's life. In the armed forces, it means having rest and regeneration after a period of combat or other hazardous duty. In criminal justice, the concern of this entry, it refers to a process whereby after arrest, prosecution, and sentencing, those who

have broken the law can be reinstated in the community with full rights restored and can desist from further involvement in crime. Thus, although there is no complete definition of what rehabilitation involves, it is usually viewed as comprising two components. One is concerned with the resettlement of discharged prisoners at the end of their sentences. The other is focused on the reduction of criminal recidivism, which applies both to prisoners and to those placed on community sentences.

This entry is primarily concerned with what is known, in terms of research, theory, and practice, about enabling individuals to achieve rehabilitation in the sense of reducing and, if possible, completely leaving behind a previous pattern of crime. Such a task is harder to achieve if there are major problems in relation to housing, employment, substance misuse, or family conflict. The penalty imposed by the court is, from a retributive perspective, intended to result in deprivation or restriction of liberty, not to remove the supports that an individual will need when trying to pursue a law-abiding life. Thus, the two strands of rehabilitation (resettlement at the end of a sentence and avoiding further involvement in crime) are mutually interdependent. They should reinforce each other, but a failure to provide for basic needs could undermine an individual's plans to stop offending.

Prison authorities in United Nations member countries have a responsibility to observe the *Standard Minimum Rules for the Treatment of Prisoners* adopted at the first United Nations Congress on the Prevention of Crime and the Treatment of Prisoners, held in Geneva, Switzerland, in 1955. Subsequently in Vienna, Austria, in December 2015, these rules were revised in a format now known as the *Nelson Mandela Rules*, in tribute to the former South African president and Nobel Peace Laureate who was imprisoned for 27 years. Rule 107 states that “[f]rom the beginning of a prisoner's sentence, consideration shall be given to his or her future after release and he or she shall be encouraged and provided assistance to maintain or establish such relations with persons or agencies outside the prison as may promote the prisoner's rehabilitation and the best interests of his or her family.” Several other aspects of the process of prison aftercare are also specified in the rules.

Of course, many of those sentenced by courts are not incarcerated but are given community penalties. The majority continue to live at home, although some may be required to reside for a fixed period in designated accommodation, such as a probation hostel. If individuals are to be enabled to avoid illegal activity, their sentences too should contain possibilities for rehabilitation. For those on community sentences, issues of housing, family contact, employment, and other areas of life should be less disrupted than for prisoners. They may be placed on probation or youth justice supervision, which requires them to report to the police, a supervisor, or youth worker. In more stringent cases, they may be required to attend weekly sessions of a group program at a drug treatment clinic. For returning prisoners (more than 700,000 each year in the United States), circumstances are different. Depending on the amount of time served, circumstances may be completely unrecognizable compared to the situation they left behind some years earlier.

Research on Reducing Reoffending

Extensive evidence shows that rehabilitation in the sense of reducing criminal recidivism can be successfully achieved. Several approaches to working in prisons, community corrections, and youth justice have been evaluated in terms of this objective. There are many studies of the impact of interventions designed to reduce rates or seriousness of offending by adults and young people, men and women, and individuals from different ethnic groups.

Typically in studies of this kind, a cohort of individuals who have broken the law is divided into two subgroups. Ideally, they will resemble each other in key characteristics (in research terminology, the groups will be *matched*). One subgroup, denoted the *experimental group*, is provided with some form of intervention that researchers or policy makers think might have an effect and which they want to evaluate. This could be any one of a wide range of activities. There are studies of basic education, higher level education, counseling, vocational training, psychological therapy, skills training, drug treatment, and special diets. Alternatively, the intervention could be some type of punitive sanction, such as a physically

demanding regimen in an institution. The other subgroup, usually called *business or treatment as usual*, is dealt with in the more routine way and is effectively an untreated comparison or control group.

After the intervention has been delivered, the two groups are compared on some dependent variables. Given the core objectives of the criminal justice system, the central outcome of interest is usually the rate of reoffending after a fixed period. The latter might be anything from 1 month to 5 years, though 1 year is more typical. However, many other variables can be (and have been) measured. The object of the exercise is to test whether the two groups differ at the end of the study and on follow-up and, thus, whether the experimental activity had an impact. This is a simplified account of the research process, and there are many features of doing it that can vary a great deal between studies. The rigor of the design that is used can be a crucial factor when interpreting the results. Researchers devote considerable time to thinking about how well (or how badly) evaluation studies are done and whether the findings reflect a fair test of the intervention that was being evaluated.

Once a number of research projects have accumulated on a given question, it is useful to appraise whether there is any evident trend among the findings obtained. That process is called *research review*, and there are several ways of doing it. The underlying idea, however, is essentially simple. In a way, it is an attempt to see the *big picture* of what is happening. Within each study, there will be a measure of the difference between the two groups (experimental and control) at the end; this is called the *effect size*. In a review, the effect sizes from different studies are aggregated together utilizing the methods of *meta-analysis*. This generates a *mean effect size*. Many other analyses can be conducted to test the robustness of this, for example, comparing studies with different designs, sample sizes, or lengths of follow-up. If the groups were not well matched at the outset, to some extent even that can be taken into account and corrected for in statistical analysis. With enough data sets, it may also be possible to analyze *moderators*, other kinds of differences that could have influenced the outcome. They include demographic characteristics of the participants (e.g., age, gender, ethnicity), criminal history

variables (e.g., type of index offense, estimated risk of reoffending), locations where the intervention was tested (e.g., prison, community), aspects of service delivery (e.g., intensity of programming, level of training of the staff, quality of delivery), and aspects of the research methodology (e.g., random allocation, quasi-experiment, before-and-after design). These facets need to be understood to obtain a clear picture of whether observed effects are genuinely attributable to the intervention rather than anything else.

Enough studies and reviews have now accumulated to draw some pivotal conclusions about several prominent issues in this field. The earliest attempts to review the effectiveness of offender rehabilitation date back to the 1950s, but the research available then was limited in both quantity and quality. A large-scale review published in the 1970s, which found numerous positive findings, was widely misreported and misrepresented. From 1985 onward, however, the techniques of meta-analysis began to be applied in this field, and the steady growth of findings and reviews since then has made it extremely difficult, if not impossible, to hold to the view that nothing works to reduce recidivism. By 2012, there were more than 100 published meta-analyses in this area, and several more have appeared since then. Many researchers in the field have therefore recognized that the volume of research on offender rehabilitation and behavioral change is sufficient for corrections agencies to draw meaningful conclusions concerning what works to reduce recidivism and increase public safety.

Some of the principal conclusions that can be drawn from the assembled literature on rehabilitation include the following. First, statistically significant and clinically meaningful reductions in reoffending can be achieved. Across the many hundreds of studies that have been published on this subject, those in treatment groups on average have a recidivism rate that is roughly 10% lower than those in untreated control groups. Second, if that figure seems rather unexceptional, it is important to remember that it is an average, summarizing a range of outcomes, including some in which experimental group participants reoffend more often than their comparators. The interventions that pull the grand mean down in this way are predominantly ones that use punitive sanctions or

other types of deterrent measures. Third, the converse of this is that there are other interventions that have notably larger positive outcomes. There are studies that have found decreases in recidivism of 50% or more; that is, the rate of reoffending among the intervention group was sometimes less than half that of the controls. Criminal justice is a challenging area to conduct rigorous outcome research. Although some studies have had fairly weak designs, these findings have also emerged from numerous randomized experimental trials and high-quality quasi-experiments.

From Research to Theory

The most influential theoretical framework for understanding the variety of findings obtained from these different interventions is the General Personality and Cognitive Social Learning perspective of Don Andrews and James Bonta. The General Personality and Cognitive Social Learning is a theoretical account of the factors associated with the development and maintenance of involvement in delinquency and crime. From this standpoint, crime (in common with many other patterns of behavior) is learned. The best explanation of how that occurs draws on a synthesis of behavioral and cognitive social learning theory. A large volume of psychological and criminological research supports this view.

Translated into terms in which these ideas can be applied in offender rehabilitation, the authors produced a specific set of proposals collectively formulated as the Risk-Need-Responsivity (RNR) model. It is worth noting that this is not itself a theory. Rather, it is a set of recommendations derived from theory (the General Personality and Cognitive Social Learning). It proposes that interventions are more likely to succeed in lowering criminal recidivism and promoting rehabilitation if they take three principal factors into account. The RNR model began on the basis of three core principles: risk, need, and responsivity. In its 2017 recent iteration, taking progressively more sets of research findings into account, this has expanded to encompass 15 principles.

The first three principles are described as *overarching*. They emphasize the importance of operating within an ethical framework that expresses respect for persons and of basing intervention

programs on empirically sound psychological theory. Principles 4–12 draw on numerous features of that theoretical and empirical background. They underline the crucial importance of assessing each individual's risk level for further offending, using well-validated methods. Alongside this, there should also be assessment of *criminogenic needs*, risk-related variables that are associated with future reoffending risks. The provision of intervention programs is guided by the principles of general and specific *responsivity*, in attempting to ensure that programs employ behavioral, social learning, and cognitive behavioral methods and strategies for influencing change and building skills. They should also take account of relevant individual strengths and of personal and cultural differences in allocating individuals to specific types of rehabilitative programs. There should be a clearly delineated link between what is learned from individual assessment and the targets that are set with them for intervention.

The final three principles (13–15) are concerned with organizational issues. They include a recommendation that services be based in the community as far as possible, training practices be cultivated that generate high-quality relationship skills among correctional staff, and management procedures be adopted that provide effective systems of support for all the other activities. To secure positive outcomes, it is also vital that there is high-quality delivery of services, the integrity of which must be monitored and sustained. When services are provided according to these principles, and if program quality and fidelity can be maintained, doing so is reliably associated with better outcomes in terms of rehabilitative aims.

These findings highlight the useful distinction between *programmatic* and *nonprogrammatic* features of the process of rehabilitation. The former refers to the design and contents of interventions themselves, such as the sessions of a cognitive behavioral skills program. The latter refers to contextual, organizational, and other surrounding factors that, regardless of a program's potential effectiveness, must be taken into account if it is to succeed. Those issues have not always received the attention they require. However, in his 2011 publication, "The Impact of Nonprogrammatic Factors on Criminal Justice Interventions," Andrews sought to remedy this by examining how they

influence outcomes and how they need to be incorporated in rehabilitative efforts.

From Theory to Practice and Dissemination

Mounting evidence supports the applicability of the RNR model, not only to what is called *general or versatile offending* but also to physical violence, sexual violence, and violence toward partners. Given how closely it reflects the expanding body of research findings obtained through meta-analysis, the RNR model has had a steadily growing influence on criminal justice professionals and systems in many countries. In some jurisdictions, this has led to large-scale efforts to design and deliver structured rehabilitation programs extensively in both prison and probation or other community correctional settings. In some criminal justice services, this has been accompanied by the creation of a process of program accreditation, to ascertain the appropriateness of methods employed in this work and manage its implementation.

There is a further advantage of rehabilitative work with offenders. Some of the activities that form part of its agenda are comparatively resource-intensive. Above all else, they require skilled, well-trained, and well-supported staff as well as materials for the management of programs and services in prison and community locations. The required expenditure may seem unattainable on top of already-high penal costs. However, when reoffending is reduced, there can be considerable savings to society. Economic analysis of the benefits to be gained from effective services shows that they can be remarkably cost-efficient. In 2015, Stephanie Lee and colleagues from the Washington State Institute for Public Policy reported on a series of comparisons between different interventions in their respective benefit–cost ratios. Many interventions have been found both to lower crime rates and reduce costs. For programs that combined different forms of rehabilitation and treatment components, benefit–cost ratios varied from 2:1 to as high as 40:1, with both young offenders and adults. The most effective interventions included Functional Family Therapy and Aggression Replacement Training in juvenile justice; and cognitive behavioral programs, correctional education, and community-based drug treatment with adults. By

contrast, programs that entailed only surveillance or supposed deterrent ingredients such as *scared straight* have negative benefit–cost ratios.

In a key sense that is of major relevance to the work of criminal psychologists, offender rehabilitation works. The evidence for this is now substantial. A similar finding emerges both in general terms and for a variety of specific offense types. This contrasts markedly with the conventional approaches of punishment and deterrence, which, although ubiquitous, are an abject failure for reducing reoffending. Furthermore, rehabilitation programs are cost-effective; sums invested in them will reduce other kinds of spending later and elsewhere. None of this applies to everyone, of course, nor can it be guaranteed. That caveat applies, however, to almost every form of human endeavor. The likelihood of success can be maximized by following a number of what are now well-established principles and practices. In 2013, Francis Cullen identified a number of reasons to be optimistic about the future of rehabilitation, for example, combining the possibility of improving offenders' lives with strengthening community safety and responding to the challenging of becoming a genuinely evidence-based field. Similarly, in 2015, James Byrne, April Pattavina, and Faye Taxman proposed strategies through which rehabilitation can become the central objective of both prison and community corrections. They include, for example, legislation or sentencing reform to reduce the rate of incarceration and the recruitment, training, and retention of a new wave of correctional staff with specialized skills in delivering effective rehabilitation within correctional agencies.

REPEAT OFFENDERS

Repeat offenders are punished more severely than single-time offenders in almost all contemporary legal systems (often referred to as the *escalating sentencing rule*). In the United States, the U.S. Sentencing Commission Guidelines specifically take into account the criminal record of a defendant in calibrating the criminal sanction. In the United Kingdom, Section 143(2) of the Criminal Justice Act of 2003 dictates that previous convictions should be taken as an aggravating factor. Furthermore, this rule is not limited merely to criminal law. In tort law, namely the law applied to private disputes, judges often impose punitive damages when they believe that the defendants have repeatedly been negligent.

This entry examines the justification for the practice of punishing repeat offenders more severely than first-time offenders from three different perspectives. It first outlines the traditional approaches of common law theorists; then it examines recent attempts on the part of law and economics theorists to justify or criticize this practice, and last, it investigates the behavioral and psychological literature. As is shown, the multiplicity of considerations makes it particularly difficult to draw any clear and determinate conclusions as to whether the escalating sentencing rule is desirable.

The Lawyers' Reasoning

In a comprehensive discussion of repeat offenders, Andrew Ashworth distinguished among four different traditional approaches to the sentencing of

repeat offenders: flat rate sentencing, cumulative principle, progressive loss of mitigation, and the recidivist premium. He further showed that those approaches have been applied in different jurisdictions.

Under the *flat rate approach*, an offender's desert should be measured with reference to the crime committed in terms of its harmfulness and culpability. Previous offenses have no bearings on either of these factors and, consequently, ought not to be taken into account in sentencing. Escalating sanctions for repeat offenders violate the requirement of proportionality, which is foundational to sentencing theory and which requires judges to impose identical sentences for identical crimes. This intuition even led some U.S. lawyers to challenge the practice of escalating sanctions on constitutional grounds. In the case of *Graham v. West Virginia* (1912), the U.S. Supreme Court considered (and eventually rejected) the argument that escalating sanctions violate the Equal Protection Clause, the Due Process Clause, and the Eighth Amendment to the U.S. Constitution (prohibiting the infliction of cruel and unjust punishment) and rejected the claim that escalating sanctions violate the prohibition on double jeopardy for the same offense.

Under the *cumulative principle*, repeat offenders should be punished more harshly than first-time offenders. Typically, this approach is justified on deterrence-based grounds or incapacitation. A repeat offender demonstrated, by his or her behavior, that deterring the offender requires a harsher sanction than that required to deter other individuals. Furthermore, by incarcerating the offender, future offenses that otherwise may have been committed by the offender are prevented. Last, perhaps one could justify the principle of escalating sentencing on the grounds that repeat offenders are likely to be morally more depraved than single-time offenders, and consequently, they deserve harsher sanctions.

Under the *progressive loss of mitigation rule*, the repeat criminal loses a privilege that the first-time offender has to the mitigation of the sanction. The primary proponent of this view—Andrew Von Hirsch—argued that the primary consideration in sentencing must be the severity of the offense. The severity of the offense dictates an upper limit to the harshness of the criminal

sentence. Yet first-time offenders should be treated more leniently given the human tendency to commit *occasional aberrations*. First-time offenders have in principle the capacity to respond to the formal censure and are therefore entitled to a second chance. While the progressive loss of mitigation rule also implies the use of escalating sentencing, it imposes strict constraints on the severity of these sentences, as the sentences must be proportional to the wrongful behavior and cannot exceed the upper limit determined by the severity of the offense.

Julian Roberts developed the *recidivist premium view*. Roberts uses desert-based considerations to argue for escalating sentences for repeat offenders. More specifically, he believes that the legal censure for a previously committed offense should be considered by the offender and should serve as an educational reminder. Roberts analogizes the repeat offender to an offender who plans the offense. The failure to respect the law after a prior conviction is a distinct moral failure on the part of the criminal that deserves a greater degree of moral reprobation than a first-time offender.

The boundaries among these approaches are not always clear, and classifying a legal rule as falling under each one of these categories may be difficult and controversial. The second, third, and fourth theories endorse the scheme of escalating sanctions for repeat offenders. A real-world example of the cumulative principle are three-strikes laws that many U.S. jurisdictions have enacted. Under these laws, a person who has been convicted of three felonies would be sentenced to harsh sanctions, which exceed the standard sanction for the offense for which the person was convicted. These laws differ from each other in many ways: Some of them apply only to violent felonies; some give discretionary powers to the judge, while others are mandatory. What characterizes these laws is that often the sentence is disproportionate to the severity of the wrong for which the person was convicted. In this respect, these laws deviate sharply from the progressive loss of mitigation rule, which imposes strict constraints designed to guarantee proportionality. In contrast to the U.S. approach, the recommendations of the European Council propose a rule that endorses the loss of mitigation rule. It specifically dictates that “although it may be justifiable to

take account of the offender’s previous criminal record . . . the sentence should be kept ‘in proportion to the seriousness of the current offence.’”

There are endless variations on the ways in which these rules can be applied and the type of considerations that may be taken into account. To illustrate, Section 143(2) of the UK Criminal Justice Act mentions two such considerations. This section dictates that judges ought to consider not only the mere existence of prior convictions but also “the nature of the offence to which the conviction relates and its relevance to the current offence.” This implies that the more similar the offense is to prior offenses, the harsher the sentence should be. The UK Criminal Justice Act also takes into account the time that has elapsed since the last conviction. The more recent the prior convictions are, the harsher the sentence should be. In some U.S. jurisdictions, the laws impose a *washed out* period, after which the prior offense can no longer be used to enhance the sentence.

In sum, traditional criminal law seems to oscillate between the strict retributivist principle focusing exclusively on the culpability of the actor and the wrongfulness of this act, on the one hand, and the view that regards the repeated behavior as a distinct aggravating factor on the other. The different views examined can be regarded as forming a spectrum along which the flat rate approach takes one extreme view; the cumulative principle takes the other extreme view; and the other two views can be regarded as intermediate solutions or as different compromises between these two extremes.

The Economists’ Reasoning

Economic analysis of law investigates the efficiency of different legal rules and doctrines. Economic analysis of criminal law formulates rules, principles, and doctrines that minimize the cumulative costs of crime and the costs of precautions against crime.

Law and economics theorists emphasize social policy considerations. In evaluating the desirability of the escalating sentences principle, they evaluate the benefits and the costs of this rule. The difficulty in applying these considerations is that there are several conflicting considerations concerning the use of escalating sanctions, and the

optimal outcome hinges on factual judgments, which are typically difficult or impossible to make.

It seems that if the sanction for the first offense is optimal, there is no reason to change the penalty for the second offense. As a matter of fact, some law and economics theorists argue that repeat offenders should receive lower rather than higher sentences. This is because repeat offenders are more likely to be detected, and hence, the *expected* sanction repeat offenders face (namely, the probability of detection multiplied by the size of the sanction) is higher than that of single-time offenders, and consequently, a lower sanction is sufficient to deter them.

Other law and economics theorists provide counterarguments purporting to justify the imposition of harsher sanctions on repeat offenders. Some argue that a repeat offender has special characteristics that increase the offender's gains from the criminal activity (termed *offense propensity*). For instance, in addition to the material benefits, a criminal with a high offense propensity may derive pleasure from harming others. The higher the illicit gain, the more likely the criminal is to engage in the harm-creating activity and the higher his or her offense propensity. The high gains of such an actor require increasing the sanctions to provide optimal deterrence. Others argue that penalties should be lesser for first-time offenders because of the increased risks of erroneously convicting first-time offenders.

Furthermore, it has been argued that escalating penalties may be efficient if the probability of detection is lower for repeat offenders in comparison to first-time offenders due to their increased experience. Repeat offenders are likely to be more talented criminals, that is, less likely to be caught and more capable of succeeding in their criminal activity. By committing crimes despite the prospects of punishment, the criminal may indicate that the benefits to him or her are larger than the costs due to the criminal's greater criminal expertise or talents.

Given the coexistence of conflicting considerations that support the escalating sanctions rule and that militate against this rule, it is difficult to make any firm conclusions as to the optimal rule. Balancing these considerations requires more information about the world, the psychology of

criminals, and their perceptions than is currently available.

The Reasoning of Behavioral Sciences

Given the skepticism concerning the cogency of law and economics arguments, psychologists and behavioral economists purport to provide arguments concerning the optimal legal rules on behavioral or psychological grounds. Criminal law is designed among other goals to deter people; hence, it is argued that one ought to understand the ways people understand and react to different norms. Furthermore, it is argued that individuals' reactions do not always fit into the rigid rationalist framework developed by economists. Yet the conclusions of these behavioral arguments are as indeterminate as the conclusions of traditional economic arguments.

Some behavioral scientists use the known finding that individuals tend to be overoptimistic and also that they are disposed to make factual judgments on the basis of salient facts—ones that they can easily recall. Applying this finding to the present context may imply that decreasing sentences are superior to escalating ones. A person who has a prior conviction is less likely to be optimistic about his or her prospects to evade future convictions, and furthermore, the person's prior conviction may provide a salient reminder of the potential costs of crime. Hence, such a person is less likely to commit future crimes.

There are, however, some behavioral arguments that support the practice of escalating sanctions for repeat offenders. First, it has been argued that the aggregate punishment faced by a criminal comprises legal and social sanctions. It seems probable that the magnitude of the social sanctions declines with each successive offense. Hence, if an identical criminal sanction is imposed on a first-time offender and a repeat offender, the latter is more likely to commit the offense because he or she is not exposed (or less exposed) to the costs of social stigma.

It is also known to psychologists that individuals tend to adjust quickly to new circumstances such that dramatic changes in one's life do not radically change one's happiness (termed *hedonic adaptation*). Individuals expect that receiving a large amount of money would greatly increase

their happiness. Yet research indicates that this is false. Similarly, individuals predict that their lives would be ruined by a serious disease or by being paralyzed. Yet the level of reported happiness after such a catastrophic event does not differ radically from the level of happiness before such an event. Hedonic theorists of criminal law inferred that in the long run, prison would have little effect on the happiness of convicted criminals. Arguably, this observation has important implications with respect to repeat offenders. Because repeat offenders have experienced prison, they may have learned that they suffer in prison less than they expected, and consequently, it could be argued that to provide optimal deterrence their sanctions need to be increased. It seems, therefore, that behavioral arguments are as indeterminate as those that rest on economic reasoning.

Conclusion

In evaluating the practice of escalating sentencing, one can use two types of arguments: Some arguments are instrumental; they rest upon the degree to which the doctrine of escalating sentences contributes to the realization of important goals such as deterrence and rehabilitation. Other considerations are principled; they rest upon one's perception as to the circumstances under which it is legitimate to impose sanctions on individuals. The multiplicity of considerations is a great challenge to criminal law theorists and practitioners, and the difficulty in balancing different considerations guarantees that future debates concerning escalating sentencing will be as lively as they have been so far.

Court Cases

Graham v. West Virginia, 224 U.S. 616 (1912)

RESEARCH IN CRIMINAL PSYCHOLOGY

Criminal psychology is a broad field that overlaps with several subareas of psychology, including correctional (applications to prison settings) and forensic (applications in courtroom settings) psychology. A widely used umbrella term, *psychology-law*, also reflects the interdisciplinary commitment of researchers in criminal psychology, who draw from many traditional domains of psychology, including clinical (e.g., assessment, treatment); social (how people and contexts influence us); cognitive (how we think and make decisions) and developmental (how we grow and change); and neuropsychology (the biological basis of behavior). This entry provides an overview of criminal psychology by exploring the shared reliance on scientific method characteristic of modern psychology, introducing contemporary research in criminal psychology sampling the major research methods in the field, emphasizing the importance of evidence-based approaches, and outlining several areas of future research.

Many people are often surprised that the field is so heavily grounded in science, both in its strategies of seeking and verifying *facts* and in its breadth of subject matter. Psychology is not, as some skeptics have surmised, merely *common sense*. The abundance of counterintuitive research findings and countless unanticipated breakthroughs in understanding complex behavior attest to the unique value of contemporary psychology. Likewise, the field of criminal psychology has moved away from its prescientific roots that often mirrored popular declarations about crime and criminals. The field has strived to replace superstitions with empirically derived insights about why some people break the law, act violently, and are undeterred by the threat of punishment.

To advance our understanding, science must regularly challenge speculation and *common sense* and use research findings to inform practice. For example, in assessing offenders at multiple points of the justice process (e.g., arrest, trial, sentencing, placement, treatment planning, prediction of risk), up-to-date tools are increasingly designed to answer specific psycholegal questions, rather than offering broad statements and using tests never intended to address the issue. Such instruments also are expected to meet a high threshold of reliability and validity, thereby minimizing subjectivity and raising confidence in their accuracy and fairness. The field has also done much to rebut the widely held perception that offenders comprise a unitary cluster. Since roughly the 1990s, cumulative evidence has revealed multiple pathways to criminal behavior, pathways that imply different prognoses and individualized targets of intervention. Similarly, both legal sanctions and the provision of specific behavior change programs have been increasingly subjected to outcomes evaluations, including cost–benefit analyses.

Why Some People Become Criminals and Others Do Not

Lawbreaking is not a rare event, and the range of crimes as defined by legal codes is vast. Strategies adopted to deter or reduce crime necessarily draw from assumptions about why people commit crime, who these people are, and how society responds to them. One set of answers has resulted in a far-reaching network of prisons created to

isolate people from society, primarily for the purposes of rehabilitation and/or punishment. The rationale for this type of closed environment was heavily promoted by early psychological theory and supported by theological stances and basic legal principles—namely, that individuals freely choose to engage in prohibited behavior and are thus responsible for their actions and the ensuing consequences. Although most clinicians and researchers historically have had some faith in the capacity of offenders to change, the choice of methods to promote that change has been controversial since the early 1800s.

In contrast to legal and theological perspectives for understanding and responding to crime, psychology has moved toward a notably analytic stance and concerned itself with broader questions of causation, intervention, prevention, and evaluation. Because the field has evolved as a behavioral, social, and biological science, psychologists are inclined to apply an objective and multifocal lens to matters of crime and punishment. For example, research in criminal psychology has shown that the exclusive focus on individual, person-centered factors does a poor job of explaining criminal conduct or predicting future criminal behavior. It is clear from thousands of psychological studies that social and environmental contexts are also critically important.

The power of context can overwhelm personal traits or become triggering events that interact with individual predispositions. A clear example of the former was demonstrated in the Stanford Prison Experiment in which randomly assigned student *guards* began to engage in abusive behavior toward their fellow student *inmates*. Likewise, the potential negative outcomes predicted by certain youthful traits can be substantially accelerated if the youth faces a violent home life which, in turn, increases the likelihood of aggressive behavior. Context is not limited to one-time events (i.e., triggers) but rather can be cumulative over time. For example, the more one smokes, the greater the risk of contracting lung cancer; continued exposure to violence has a parallel negative risk effect. Thus, both individual factors and environmental context must be catalogued in the list of risk factors. Which of these exerts more power at any given time has become a central question in criminal psychological research.

Although psychology and other clinical sciences originally followed a medical model with a focus on singular *causes*, a more useful perspective has been the previously noted identification and weighting of multiple *risk factors*, factors that increase the probability of a given behavior or outcome. Not all smokers become cancerous, but smoking certainly increases one's chances. Adopting a public health model (i.e., combining risk and protective factors) has proven quite valuable in understanding, predicting, and designing interventions for preventing and reducing criminal behavior.

Some of the best statistical predictors of who becomes a criminal and who does not include the social and environmental contexts into which people are born, grown, develop, and confront on a daily basis. Ethnicity, poverty, and other forms of social and economic disadvantage have a cumulative effect on *risk* for crime and incarceration. Studies have found a strong link between social and economic inequality and violence, as well as between social rejection, aggression, and impaired thinking abilities. It is also clear from several studies that head injuries are related to aggression, cognitive impairment, and imprisonment and that people from disadvantaged settings are more likely to sustain head injuries throughout their lifetimes. This collection of findings is a good example of how individual and context risk factors interact to influence criminal activity.

Another substantial body of research in criminal psychology has consistently revealed eight risk factors that increase the likelihood of criminal behavior. The identification of these factors is drawn from scores of studies that assessed dozens of offender characteristics and those of their families, associates, community environments, and so on. Four factors are especially robust predictors: a history of criminal behavior, procriminal attitudes (i.e., thoughts, values, and beliefs that support criminal behavior), procriminal associates (i.e., one's circle of associates who espouse procriminal attitudes), and antisocial personality (i.e., lack of self-control, pleasure-seeking behaviors, disregard for others). Further evidence of the validity of the *big four* is provided by treatment outcome studies. When these factors are successfully targeted, delinquents and adult offenders are much less likely to reoffend than if these factors are not

addressed. The additional components of the *big eight* are lack of prosocial achievement (e.g., employment, education), family or marital discord, substance abuse, and lack of prosocial hobbies or leisure activities. As will be discussed later in this entry, the targeting of dynamic (i.e., changeable) risk factors, primarily through social cognitive behavioral therapies, promotes more positive outcomes than many historically popular but often counterproductive approaches.

An important note is that many of the relationships identified in broad studies are correlational and thus do not establish direct causation. For example, despite the positive relation found between poverty and crime, or between lack of educational achievement and crime, it cannot be concluded that being poor or dropping out of school directly causes crime. Exceptions to these links are certainly plentiful. Moreover, other variables may actually better explain a given relationship. For example, there is a positive relation between ice cream consumption and death by drowning, a puzzling connection at best. It is hard to imagine that eating ice cream causes people to drown. Rather, a *third variable*, namely, summertime, is the more logical common underlying factor. In the case of poverty and crime, underlying *third variables* might include social rejection, tumultuous community environments, or procriminal associates. The search for causal silver bullets is rarely satisfying. Examining the joint influence of individual traits, abilities, and temperament combined with family, social, and community contexts of a person's life provides a better understanding of his or her likelihood of becoming a criminal and of reoffending. As has been suggested, the goal of preventing and reducing crime is better served through both addressing personal traits and altering negative contexts.

The validity of this interactionist perspective could be challenged if research were to reveal powerful individual traits that seem to override context or, alternatively, to identify engulfing environments that overwhelm personal traits. An example of the former is the apparently treatment-resistant personality of the psychopath. The public often imagines that psychopathic personality is at the base of most crime. Indeed, one hallmark of psychopathy is antisocial behavior. People with psychopathic personalities (whether incarcerated

or not) generally have an inability to feel empathy for others, show callous emotional responses to situations that bother others, are impulsive and reckless, and are superficially charming and manipulative. Although psychopaths comprise only about 15% of the criminal population, they may account for a much higher proportion of crimes and are also notably poor candidates for even the most well-researched, evidence-based treatments. However, those who can avoid violence and other criminal acts, and who have sufficient intellectual resources, may well rise to the highest ranks of employment in fields where their lack of prosocial emotions gives them a competitive advantage.

Research Methods in Criminal Psychological Science

Studying criminals is not easy or straightforward. With good reason, offenders are protected by layers of rules; researchers must apply ethical standards including human subjects' safeguards. These rules evolved, in part, because of historical abuses in which prisoners were used as *guinea pigs*. A grossly inhumane example is the experimentation by Nazi doctors who forcibly tested the human body's response to various chemicals. A less obvious example, in the context of an impoverished prison setting, is drug testing. In such studies, enrolled offenders neither had a truly free choice—the token pay offered by pharmaceutical companies stood in stark contrast to inmates' lack of funds—nor were they fully informed about the potential risks of experimental medications. Contemporary rules about how researchers are allowed to work with human subjects also come directly from studies in criminal psychology—and a well-known example is the Stanford Prison Experiment referred to previously.

The Stanford Prison Experiment was conducted in the early 1970s by social psychologists who wanted to better understand the behavior of prisoners and guards, particularly in relation to each other. The researchers randomly assigned healthy Stanford undergraduates to be either a guard or a prisoner and placed them together in a converted campus basement *prison*. The participants' behaviors became so extreme that the study was canceled well short of its planned duration.

Guards began abusing *inmates*, and inmates began rioting and experiencing mental health problems. The researchers observed additional harmful outcomes to participants who had been allowed to go *off script*. Although the students were subsequently debriefed and counseled, it was apparent that the experience would not be easily forgotten. This historic experiment served both as an emblem of the powerful impact of prison environments and as a stark warning to researchers to anticipate and prevent harm to their participants. Ethical standards about how researchers are allowed to study humans owe much to the growing awareness and correction of past abuses.

Decisions Researchers Make About Research Methods

For all research, the unit of analysis must be determined. Studies in criminal psychology are not different. Some research questions focus at the level of individual persons (e.g., assessing which types of offenders are more likely to be violent), or they may take a broader focus, at the level of a system (e.g., comparing the violence rates in different types of prisons). Often, a study will include multiple levels of analysis to provide a view of interacting factors. For example, researchers might examine whether a cognitive therapy program has different effects on intellectually impaired inmates versus those who have average or above average abilities.

Another decision facing researchers is the choice of study design. For example, researchers interested in how children of prisoners are affected by their parent's incarceration could approach this question in different ways. They could survey a sample of prisoners' families at a given point in time (e.g., by mailing out questionnaires or conducting interviews and then analyzing the results). This *snapshot* is relevant to that particular point in time, but it could not assess changes over time. To address the question of how children's experiences of their parent's imprisonment may change (e.g., Does it get progressively worse? Do children adjust? Are there factors that reduce or amplify negative impact?), the research design requires that data be collected and analyzed across time. Because the answers to these questions may well have implications for public policy, careful

attention to design and measurement is critical. Whether addressing basic or complex questions, researchers in criminal psychology need to have a solid understanding of research methods.

The Progressive Movement to Evidence-Based Approaches

The kinds of studies cited in this entry provide a growing base for decision-making. Research in many fields of psychology, including criminal psychology, has as a goal not only the understanding of behavior but also the application of findings to human well-being and sensible public policy. Especially in the criminal justice system, public policy has often reflected widespread social attitudes and popular opinions rather than evidence-based findings. For example, the *get tough* movement of the last third of the 20th century, emphasizing harsh punishment, has had a series of unintended consequences including economic black holes, overreliance on incarceration, and worsening offender outcomes. A good example is boot camp programs, where juveniles who were sent to military-style settings actually learned tricks of the trade and reoffended at higher rates than youths who did not attend these types of programs. The value of research in this context is to examine the actual outcomes in comparison to the hoped-for results. *We think this ought to work* is no substitute for research that helps identify *what works*.

Interestingly, the retreat from the mid-20th-century goals of rehabilitation was itself fueled by *studies* that collectively showed no difference in recidivism rates between *treated* and *untreated* prisoners. Although the *get tough* trend has persisted since the 1980s, subsequent reanalysis revealed two critical research flaws: First, the studies compared offender groups of unknown equivalence, and thus the validities of results were likewise unknowable. Appropriate control groups, admittedly hard to engineer in justice settings, are the gold standard in treatment outcomes research. Second, many early so-called rehabilitative interventions were, by 21st-century standards, quite weak. In addition, treatment providers or supervisors often failed to monitor whether treatments were actually delivered as intended. Thus, many of the studies underlying the *rehabilitation doesn't*

work conclusion failed to provide trustworthy results. Bad science may have supported bad policy.

From these flaws, researchers now recognize how critical it is to closely monitor treatments in terms of their duration, intensity, client attendance, engagement, and expertise of the interventionists. Consider a cooking parallel: The latest cake recipe in your favorite magazine is touted to be a good one. As a beginner, you try it out, and the result is mediocre at best. Do you discard the recipe? Perhaps, but only if you can document that your instructional guide (the recipe) was printed correctly, that you followed all the sequential steps, and cooked the ingredients long enough and at the stated temperature, in a reliable oven, while also accounting for your status as a kitchen beginner. The plausible alternatives to the *bad recipe* verdict are manifold.

The lessons of this example demonstrate the need for rigorous requirements if studies are to be used as a basis of policy recommendations. The standards include the requirement that comparison groups (Treatment X vs. Treatment Y) must be as equivalent as possible on all important measures (e.g., age, crime history, learning capacity) so that any differences in outcomes are likely to be the result of intervention and not characteristics of the offenders. Alternatively, it would be important to know if Treatment X might prove beneficial to certain subgroups but not others. Such studies have provided clear evidence, for example, that *high-risk* and *medium-risk* offenders are much better targets for intensive intervention than *low-risk* individuals who, it turns out, may actually be harmed by further immersion in the justice system.

Proposed interventions also must derive from reputable psychological theory and previous preliminary findings. The components of an intervention (the recipe) must be clearly elaborated. *Six months of group therapy* is disqualified because of its vagueness. Even if treatment *success* were achieved at prison X, it must be asked whether therapists at prison Y have the same approach to group therapy. To combat the vagueness and subjectivity problem, treatment staff must adhere to a sufficiently detailed *treatment manual*. Adopters of evidence-based interventions are routinely required to undertake

extensive training. Treatment providers not only need to show expertise in the intervention details but must also maintain an acceptable level of engagement and quality control so as not to *drift* or lapse into providing a watered-down version of the treatment.

Researchers also must decide what *results* to look for. Suppose that an offender–client learns to recite the principles of *Thinking for a Change* (a cognitive behavioral program)—a good first step. However, it is more critical to assess whether knowing principles is accompanied by changing target behaviors, for example, being less impulsive and less aggressive, both during practice sessions and in the live environment. Ultimately, researchers are interested in whether the intervention results in crime reduction. Collateral damage may also be an important result to track. In many cases, *treatment as usual* (i.e., the status quo of current conditions) has been shown to have negative, iatrogenic effects, causing actual harm. Likewise, persons enrolled in a given treatment program might quickly reach a benefit ceiling, particularly if their everyday environment runs strongly counter to the thrust of the intervention.

Finally, all treatments and nontreatment interventions have associated costs. In a few jurisdictions, social and governmental costs are calculated and compared across interventions. For example, the costs of confining youthful offenders to an institutional program are compared to the costs of enrolling them in an evidence-based, multisystemic community program. In many cases, reputable interventions show not only better outcomes but a notable return-on-investment savings. In other words, for every dollar spent in program X, the state saves Y dollars. This kind of telling demonstration helps promote the original goal of contributing to informed public policy.

The Future of Research in Criminal Psychology

Psychology is well positioned to provide a deeper understanding of crime and to promote changes in justice policy. The prison system has outgrown the country's capacity to sustain it. Just as America looked to psychology in the early 1800s to form the foundation for justice policy as a focus on

individual people's actions that required punishment and rehabilitation, America may again draw from psychology while prisons are reinvented. Psychological science has shown that the *contexts* in which people live (i.e., critical environmental factors that promote and sustain criminal behavior) cannot be ignored. Both individual characteristics (e.g., the *big four*) and harmful contexts, such as violence, substance abuse, poverty, and lack of means or ability to change one's contexts, are all associated with higher risk of criminal outcomes. In contrast, interventions aimed at changing personal procriminal factors as well as those promoting positive environments have been shown to reduce the risk of criminal outcomes.

Public policy has been slow to follow these advances. More so than in many other fields, justice policies often reflect popular sentiment rather than evidence. Beliefs about *what works* are notably subjective and typically grow from entrenched personal and cultural attitudes. Consequently, proposals to implement empirically supported approaches to crime and delinquency are often met with resistance. Thus, researchers are called on to persistently and thoughtfully translate research evidence in a manner that promotes its recognition and adoption.

Notwithstanding the major insights from research in criminal psychology discussed previously, many questions remain. Among them is the unique challenge presented by offenders with mental disorders, a group that now comprises a substantial and growing proportion of jail and prison inmates. Logically, intervention programs would address both criminal behavior and treatments for mental disorder. Likewise, even though drug offenders represent another huge segment of inmates, treatment outcome studies have lagged behind. There are little data regarding how community versus institutional substance abuse treatments for offenders compare. Sparsely available too are studies examining the impact of correctional staff attitudes and day-to-day practices on inmate behavior. Noxious prison environments, including those where sexual assault is prevalent, can be an overriding factor that sets a low success ceiling to even the best available programs. Similarly, what is the potential of community-based treatment extensions? How can citizens become more attuned to and willing to consider research

evidence? Future research may be able to help answer some of these questions. Insights from the science of criminal psychology may change the direction of how America deals with crime and its consequences.

RESILIENCE AND POSITIVE PSYCHOLOGY

Positive psychology research has outlined a set of basic psychological needs that all humans strive for and the conditions under which these needs are most likely to be satisfied. Relatedly, the study of resilience is concerned with identifying how some individuals are able to adapt positively in the face of significant adversity. The study of both resilience and positive psychology emerged as a response to mainstream psychology's tendency to focus on avoidance of negative symptoms and outcomes. This entry reviews the major insights garnered from these two subfields of psychology and how they are increasingly being applied to interventions aimed at reducing criminal behavior.

Positive Psychology

The field of positive psychology is about exploring the conditions under which humans are most able to flourish and live a good life. It emerged as a response to the disease-centric view of psychology that had become fixated on alleviation of negative symptoms, drives, habits, and moods. What the research shows is that people are not only concerned with ridding the negative but also strive for positive experiences, emotions, ambitions, and virtues that enable them to flourish. At the most fundamental level, all human beings are driven to fulfill basic human needs, for example, mastery, agency, relatedness on an interpersonal and group level, spirituality, creativity, and physical health. In situations of high adversity where these needs are threatened, it is crucial that personal resources and protective mechanisms exist and, also, that individuals are aware of and draw on these mechanisms. Absent these conditions, it is likely that defensive processes such as withdrawal from others, antisocial behavior, or self-harm will be engaged in an effort to protect the self.

Positive emotions such as joy, gratitude, serenity, interest, hope, pride, amusement, inspiration, awe, and love act as signals of flourishing. However, the field of positive psychology has shown that these emotions can *produce* flourishing as well. The broaden-and-build theory of positive emotion, for example, states that these emotions serve to broaden the scope of peoples' momentary thought-action repertoires and to build new physical, intellectual, and social resources. These resources enable people to respond to adversity in new, adaptive ways or to capitalize on opportunities, which increases their propensity for experiencing positive emotions. In this way, positive emotions are both an end goal and part of the process of being resilient.

Defining Resilience

The simplest and most widely accepted definition of *resilience* is positive adaptation in spite of serious risk of maladaptation. This definition encompasses two key criteria. The first is that an individual has, at some point in his or her life, been exposed to significant adversity that threatens the likelihood of positive outcomes. In other words, there must have been some negative stimulus to overcome; a person who has not experienced such risk cannot be classified as being resilient. In the beginning years of the study of resilience, researchers tended to focus on the impact of singular risk factors (e.g., low socioeconomic status, prenatal exposure to toxins) on maladaptation. Soon, though, it became evident that risk factors often co-occur and increase the likelihood of cumulative disadvantage over time. Even a cursory reading of literature on topics such as criminal behavior, addiction, psychological distress, among others, highlights the fact that the majority of individuals experiencing these problems have been exposed to at least one, and often several, risk factors.

Yet many who similarly experience these factors do not exhibit psychological or behavioral problems. Thus, the second criterion for the classification of a person as resilient is positive adaptation. How markers of *doing well* in the face of adversity are defined has been a contentious issue among researchers. Some argue that whether individuals meet the expectations for age-related

developmental tasks is indicative of resilience. For example, most cultures expect that between the ages of 6 and 12 years children will form friendships, engage in self-evaluation, and develop critical-thinking skills. During later adolescence and early adulthood (i.e., 18–22 years of age), it is expected that individuals will become autonomous from their parents, begin thinking about career aspirations, and internalize a concrete sense of morality. The problem with focusing solely on external indicators of resilience is that internal, psychological indicators of maladaptation may not be outwardly apparent. A number of studies, for instance, have found that while stress-resilient children outperform the stress affected on external indicators such as educational performance and social competence, many of the resilient children still experience psychological difficulties such as depression and anxiety.

Risk and Protective Factors

Researchers in fields such as developmental psychology and criminology have published extensively on studies that have identified specific risk and protective factors and their impact on the lives of individuals. Risk factors are those which, if present, increase the probability of developing a behavioral or psychological disorder. Absent these risk factors, it is expected that the prevalence of these disorders will be far less in randomly chosen persons from the general population. Protective factors, on the other hand, are those factors which can serve to ameliorate or modify a person's response to aversive conditions.

Those risk and protective factors uncovered thus far have generally been categorized in one of three domains of influence: individual, familial, and community. At the individual level, common risk factors include low intelligence and attainment, personality traits such as impulsivity and lack of agreeableness, low self-esteem, and a lack of empathy. Protective factors include high intelligence and attainment; positive appraisals of the self, such as high self-esteem and self-efficacy; future aspirations and hopes; and high emotional intelligence. Perhaps the most consistent factor in terms of its potential for both protection and vulnerability is intelligence. While it is evident that intelligence impacts educational and economic

attainment, research also suggests that it has a significant effect on the ability to think in the abstract. A person who is able to think in abstract terms is more likely to relate interpersonally and emotionally, to think critically and solve problems, and to plan for the future rather than live solely in the present.

At the family level, the most salient factors seem to be the quality of the parent–child and parent–parent relationships. Lack of supervision, harsh and/or inconsistent punishment, and abuse or neglect between parents or parents and children constitute prominent risk factors. In addition, individual characteristics such as parental psychopathology, criminal behavior, or substance abuse increase the vulnerability of children. On the other hand, prosocial parents who are loving, warm, and supportive, yet who have clear, high standards for their children and an authoritative parenting style, have a protective impact on their children, even in the presence of other risk factors.

Risk and protective factors for children and youth at the community level primarily comprise the school environment and broader community dynamics. Distrust between students and teachers, unclear and inconsistent rule enforcement, and the type of school (e.g., reformatory schools for *problem children*) have been shown to be significant risk factors for maladaptation. Community dynamics increasing vulnerability include factors such as economic deprivation, low collective efficacy, residential mobility, and cultures supportive of antisocial behavior. On the other hand, protective factors at the community level are those which provide opportunities for young persons to develop skills, connect with prosocial peers and adult role models, and communicate clear but fair community norms.

Protective Processes

One of the most crucial insights from resilience research is that identifying individual risk and protective factors does not paint a complete picture of how people overcome adversity. On both an empirical and practical level, a greater concern is understanding how these factors function to confer vulnerability or have a protective effect. For example, it is known that parental substance abuse is a risk factor for children. A parent

struggling with addiction may impart risk to his or her child through neglect or abuse, which, in turn, can lead to a depressed, anxious, or substance-abusing child. Outside the home, however, a prosocial and supportive adult role model such as a teacher or a coach may act as a protective factor by increasing the child's trust of others and enhancing the child's self-esteem and feelings of self-efficacy.

There has been a broad consensus that the role of human agency is of the utmost importance in untangling the intricacies of protective processes. The mere fact that protective factors are present does not mean an individual will utilize them. Those who are resilient are not simply impervious to risk, but they also actively engage the protective resources in their lives to help themselves overcome this adversity. Thus, interventions aimed at fostering resilience must not only create opportunities for prosocial relationship and skill development but also inspire feelings of control over one's own life.

Implications for Interventions in the Context of Criminal Behavior

Positive psychology shows that in order to live a *good life*, basic human needs (e.g., relatedness, competency, autonomy) must be fulfilled. Relatedly, resilience research has shown that individuals draw on internal (e.g., positive self-identity, social and emotional competency) and external (e.g., parents, friends, role models) protective factors to do well in the face of adversity. Taken together, these two fields offer valuable insights for developing interventions aimed at increasing positive adaptation.

In the context of criminal behavior, a plethora of research has shown that many offenders have had tumultuous family relationships, lack critical social and emotional skills, and grew up in socially disorganized neighborhoods. Evidence-based programs intended to reduce criminality recognize the intersectionality of these issues and adopt multifaceted approaches to dealing with risk and protective factors. For example, it is clear that substance-abusing parents can have a significant impact on future problem behavior of their children. Successful interventions grounded in resilience and positive psychology research have

focused not only on reducing symptoms such as depression, anger, or feelings of isolation that may lead to substance abuse but also on building skills that help parents to foster warm, caring, and supportive relationships with their children.

Developmental psychology has shown that early prevention is more effective than intervening after problems have already manifested themselves. Theoretically driven prevention programs targeted at preschool and early elementary-aged children in the classroom have proven to be especially effective at reducing problem behaviors such as conduct disorders, drug abuse, and violence. Common elements of the curricula in these programs include interpersonal problem-solving, maintaining relationships, building emotional awareness, expressing emotions positively, self-control, and building self-esteem. Teaching these skills in the classroom enhances the social and emotional competencies of young children, enabling them to deal positively with adversity rather than succumb to it.

Of course, correctional systems are filled with individuals who have already fallen victim to the multiplicity of risk factors in their lives. Resilience and positive psychological theory have also informed many rehabilitation and reentry initiatives that aim to help offenders desist from crime. There is a growing recognition among those who study desistance that focusing correctional treatment solely on avoidance or management of risk factors is not sufficient to lead to sustained behavioral change. Resilience and positive psychology research has shown that doing well in the face of adversity requires the acquisition of social and emotional capacities, in addition to the presence and utilization of external socio-structural supports. For example, the Good Lives Model of offender rehabilitation suggests that all humans seek to attain primary human goods (e.g., relatedness; excellence in play, work, and agency; creativity; spirituality). By actively engaging offenders in identifying the types of primary human goods they seek to achieve, practitioners can identify offenders' strengths as well as help them to build on their weaknesses. Helping them to develop the internal (i.e., skills and capacities) and external (i.e., social supports, opportunities) conditions to fulfill primary human goods in a socially acceptable way enables offenders to be resilient to, or avoid

entirely, the risk factors that previously drove them to criminal behavior.

RESILIENCE AS A PREDICTOR OF DESISTANCE

Rather than focusing on how negative factors (e.g., pessimism, impulsivity) contribute to offenders committing additional crimes (recidivism), many psychologists and criminal justice experts have suggested that the goal should be to examine how positive characteristics such as optimism, thoughtfulness, and altruism can increase an individual's willingness to cease criminal behaviors (desistance). As a result, measuring what influences a person's likelihood of *not* committing further crime has become more interesting to researchers. However, the factors that contribute to desistance are not merely the inverse of the variables that predict recidivism—rather, the

relationship is more complex. One factor that appears to predict desistance is resilience. Briefly, resilient individuals have the ability to positively adapt after experiencing challenging and traumatic life events. It follows that this ability to positively adapt would increase the likelihood of ending future criminal behaviors. After reviewing the research on desistance, the resilience factors most associated with ending criminal behavior will be addressed.

An Overview of Desistance

Grounded in operant conditioning, a punishment-based criminal justice system seeks to prevent criminal behavior (either one time or recurring criminal behavior) by instilling fear of punishment in noncriminals and for repeat offenders, making the costs of getting caught greater than the possible gain. As a result, criminal justice scientists began studying when and under what conditions individual and situational factors could predict the likelihood that individuals would commit another crime. This is also known as *recidivism*. For example, factors such as age, gender, socioeconomic status, and impulsivity are related to recidivism. Recidivism makes the assumption that certain individuals are likely to reoffend, and the purpose of the legal system is to stop this behavior. In other words, law enforcement officers arrest, juries convict, judges issue punitive sentences, and parole officers and prison personnel take away privileges. These outcomes are reactions to criminal behaviors meant to reduce recidivism and instill proper behavior. But what has become a more interesting question is what contributes to the avoidance of later crimes or desistance. Based on this concept, the criminology literature describes three groups of individuals: resisters (who never offend), desisters (those who offend and eventually stop), and persisters (those who continue to reoffend).

When examining criminal behavior and desistance, one of the challenges that researchers face is exactly how to operationally define desistance. For example, some researchers define desistance as not engaging in *any* subsequent criminal behavior, whereas others define it as not repeating the *same* criminal behavior. Still others define it as not

committing any maladaptive (although not illegal) behavior. Another measurement issue involves the length of time that must pass between prior and later offenses to be considered a desister. Researchers have used time frames ranging from 6 months to 3 years, to an offender's lifetime. There are also differences in how some scholars conceptualize desistance. For example, some believe desistance is a static event that should be measured at one point in time, whereas others suggest desistance is a process that encompasses a series of attitudes and behaviors that occur before an individual chooses not to reoffend. Finally, the data collected on desistance are either based on qualitative data such as interviews or observations in prison settings. Although this information is rich in detail and allows the reader to understand desistance from the offender's perspective, making predictions for many based on data of a few is tenuous. Due to these differences in definitions, comparing the desistance outcomes for one study to those of another is often impossible to do. That does not mean that desistance should not be measured. It means that scholars should continue to investigate this concept in order to strengthen the ties between positive characteristics and willingness to avoid subsequent criminal behavior.

Predictors of Desistance

Despite these difficulties in defining desistance, researchers have found that abstaining from further criminal behavior appears to be more likely for individuals who have gainful employment and for those who have separated from original peer groups. Other avenues of improved social support include new and positive relationships with family (spouses and children) as well as attending religious services. In addition to social support, desistance appears to be a function of age. For example, some offenders only engage in crime as adolescents, and of those who do continue to commit crimes through adulthood, many eventually stop as they get older. Finally, positive traits such as self-efficacy, intelligence, and resilience are related to desistance. Resilience specifically is a combination of intra- and interpersonal factors that allow a person to develop competently even in the face of adversity.

An Overview of Resilience

Early research on resilience focused on children's responses to extreme life experiences such as violence, maltreatment, abuse, and living in residential care systems. However, these early findings related to resilience have since been considered resilience outcomes (e.g., growing up in a rough neighborhood and having never been arrested) rather than individual differences that predict positive outcomes. This early research evolved into conceptualizations of resilience as a combination of traits and individual differences such as social support, commitment to change, self-esteem, positive emotions, and morale. Similar to the research on desistance, a lack of coherence in how resilience is defined has plagued researchers since the 1980s.

However, starting in the 1990s, the creation of valid and reliable measures of resilience has reduced the lack of uniformity in the construct of resilience. Measures such as the Psychological Capital Questionnaire, the Resilience Scale for Adults, and the Connor–Davidson Resilience Scale have since dominated the field. A number of researchers have attempted to unite these conflicting definitions of resilience to create an interactionist perspective of resilience. According to the interactionist theory, resilience develops as a dynamic relationship between a person and his or her environment. The three components of resilience are identified as (1) experiencing a significant stressor (e.g., poverty), (2) individual protective and risk factors that predict how a person will react to the stressor (e.g., high self-efficacy, social support, and anxiety), and (3) adapting to the stressor in a positive manner. This perspective recognizes that rather than an innate static trait, resilience is a skill that develops over time as a person interacts with aspects of his or her environment. Thus, understanding the role of resilience, or a person's ability to successfully navigate a stressful world, is a valuable lens to predict desistance.

Resilience as a Predictor of Desistance

The ability for a person to grow despite (and perhaps because of) adverse situations is not a product of luck or chance but partially a function of

resilience. Just as risk factors increase the likelihood of an individual engaging in criminal behavior, protective factors like resilience keep individuals from engaging in further criminal behaviors. Highly resilient people use protective factors to interact with their environment in more positive ways (e.g., they navigate risky situations, reach out to trusted mentors and friends, create new social support systems, and as a result are generally happier). One model commonly used to describe this process is the broaden-and-build theory of positive emotions. According to this theory, when individuals successfully navigate a stressful or negative situation, it creates positive emotions. These positive emotions act to broaden a person's thoughts and actions and urge the person toward further actions such as creating new experiences and developing novel solutions to problems. This suggests that resilience is an iterative process by which a person is successful in avoiding criminal behavior by using a new strategy, which leads to more positive coping mechanisms in the future. This theory falls under the scope of positive psychology, also known as the *study of human strengths* to promote effective functioning. Rather than trying to understand, predict, and change people at their worst, positive psychology attempts to understand, predict, and change people to become the best version of themselves.

Psychosocial Differences in Resilience as a Predictor

Individuals experiencing chronic, long-term adversity such as poverty, abuse, lack of familial support, or institutionalization tend to encounter more disruption in their lives. Among those who experience these chronic stressors, individuals, particularly adolescents, who are low in resilience are susceptible to impairments in their job performance, ability to function in society, and relationships with others. However, resilient individuals are able to successfully adapt to the acute and chronic stressors in their lives. As a result, they develop a sense of mastery that allows them to confront new stressors with confidence rather than fear. However, demographic differences such as age and gender appear to influence the influence of resilience on desistance.

Adolescent resilience and chronic adversity are not always comparable to adult resilience. This is partially due to the inconsistencies in how resilience has been defined and operationalized over the years (e.g., is resilience returning to normal, growth after trauma, or adapting positively?). Many adolescents engage in delinquent behavior as part of identity development; therefore, resilience acts as a protective factor by reducing their likelihood of engaging in antisocial conduct. It appears that times of crisis force resilient adolescents to introspect about the uncertainty and emptiness in their own lives caused by their criminal behaviors such as drug use, theft, and violent behavior among adolescents who have been institutionalized. This introspection acts as a mechanism of positive change to forge new behaviors. Resilience appears to be especially salient for individuals who engage in short-term delinquent behavior; they are more likely to be resilient and thus desist from persistent criminal behavior. However, among adults, resilience as a predictor of desistance functions differently. Rather than introspection, resilient adults are empowered to make more positive decisions such as finding new social support systems and locating employment.

There may also be gender differences in desistance. For example, resilience has been proposed as a mechanism by which women cope with stressful environments. Women who successfully seek out social support can improve their resilience, which makes them better able to seek out further social support. This may allow women to develop new cognitive and behavioral strategies such as creating a new identity, finding resourceful methods to cope under stress, and improving their self-efficacy. Over a period of time, resilience may be mutually reinforcing.

Conclusion

Fostering positive traits like resilience in an effort to support desistance from crime is a growing area of interest. Helping adolescents identify protective factors associated with resilience will allow them to recognize that they can develop skills from the obstacles they face, which in turn will empower them to make decisions that lead away from criminal behavior. Rehabilitation suggestions for increasing resilience in adolescents include strengthening social support for adolescents

(trusted adults such as mentors, strengthening family ties, education, and employment). In contrast, adults have different needs. For adults, social support and family ties are still important, and education and career support for ex-offenders is essential. Learning to avoid risks, form new friendships, and refrain from deviant behavior requires positive traits such as resilience.

RESPONSIVITY PRINCIPLE

According to the Risk-Need-Responsivity (RNR) model, the effectiveness of correctional rehabilitation programming is a function of a program's level

of adherence to the model's three central principles: Risk, Need, and Responsivity. The Risk principle addresses who should receive correctional treatment services (i.e., high-risk offenders). The Need principle answers the question of what should be the focus of correctional treatment services (i.e., criminogenic needs). The final principle in this model, known as the *Responsivity principle*, answers the question of how correctional treatment services should be provided by identifying the types of interventions that are effective at reducing criminal recidivism among criminal justice populations. According to the Responsivity principle, interventions that address criminogenic needs among high-risk offenders will be most effective when the style and mode of the correctional intervention is matched to the learning styles and abilities of offenders.

According to the RNR model, the Responsivity principle has two levels. The first level, the General Responsivity principle, focuses on what types of services are effective at reducing criminal justice involvement in offender populations in general. The second level of the Responsivity principle is called the *Specific Responsivity principle*. This principle focuses on individual factors related to the offender or the environment in which the correctional services are delivered that can impact the outcome of otherwise effective correctional interventions.

General Responsivity Principle

The General Responsivity principle draws on over 500 research studies and meta-analyses of correctional programming to identify interventions that are most effective at helping people to learn and engage attitudes, beliefs, and behaviors that support noncriminal choices. This research has found that cognitive behavioral interventions that engage social learning methods consistently produce the largest reductions in criminal recidivism. Correctional programs that engage these approaches to treatment have been found to have significant impacts on criminal recidivism, with estimates of reductions in criminal recidivism ranging from 20% to 55% for program participants.

The cognitive behavioral programs that address criminal recidivism in correctional programming typically use some combination of cognitive

restructuring and cognitive skills training techniques to help participants identify and correct thinking patterns that lead to their involvement in criminal behavior. These interventions also teach interpersonal problem-solving and critical reasoning skills needed to support noncriminal behaviors. The social learning methods used in cognitive behavioral programs for offenders provide participants with the support necessary to develop and master the social, cognitive, and interpersonal skills that are needed to change the attitudes and behaviors associated with criminal behavior. These social learning methods include techniques such as skill modeling through live demonstrations, hands-on practice through activities such as role playing and rehearsals, and behavior shaping techniques such as positive reinforcement methods.

Some of the best known interventions that incorporate the principles of the General Responsivity principle are Reasoning & Rehabilitation, Moral Reconnection Therapy, and Thinking for a Change. Each of these interventions uses cognitive behavioral intervention techniques and social learning methods to target one or more of the major criminogenic risk factors (i.e., antisocial behavior, personality, cognition, and associates). All three interventions provide a structured, manualized, time-limited, group-based intervention that engages differing combinations of cognitive restructuring, cognitive skills training, problem-solving therapies, and structured learning experiences.

The General Responsivity principle is built on the notion that the type of intervention provided to offenders and the environment in which these interventions are enacted impacts a program's outcome. Some of the most common discussions of the General Responsivity principle focus on the treatment interventions that produce positive outcomes in correctional rehabilitation. However, some research has also focused on types of staff practices that can increase the therapeutic potential of correction programming. These practices include five recommendations for how staff should behave during the delivery of correctional programs, which are often referred to as *core correctional practices*. The first recommendation focuses on correctional staff's use of authority. According to this recommendation, correctional practice is optimized when staff use authority in a firm and

fair manner, in which rules are applied in a consistent and transparent fashion. The second recommendation focuses on the need for staff to model antiracial behaviors. Staff can carry out this recommendation by demonstrating these behaviors—through their own words and actions (i.e., modeling) as well as by reinforcing participants' positive behaviors. The third component of core correctional practices involves teaching offenders concrete problem-solving skills. This recommendation calls for staff to offer concrete guidance and coaching on ways to deal with situations and factors that impede an offender's ability to engage in noncriminal activities. The fourth recommendation focuses on correctional staff assisting offenders in accessing community resources. This recommendation requires staff to help to facilitate linkages to community services and to help offenders advocate for services when necessary. The last practice recommendation related to core correctional practices focuses on correctional staff's need to develop professional relationships with offenders that include open, warm, and positive forms of communication. This approach to relationship development is believed to optimize the interpersonal influence that staff can exert over offenders during the treatment process. Research suggests that core correctional practices are most effective when engaged within the context of programs that adhere to the principles of the RNR model.

Specific Responsivity

The second level of the Responsivity principle focuses on factors that could impact the outcome of an otherwise effective intervention. According to this principle, the cognitive behavioral techniques that are found to work in general may need to be modified to account for individual-level characteristics that could impact an individual's ability to initiate, engage, complete, and benefit from an intervention. The writings most closely associated with the development of the RNR model have identified several specific responsivity issues that require consideration. These include an individual's learning style, gender, personality, and motivation. However, the list of specific responsivity issues in correctional programming continues to grow and much is yet to be learned about the best

ways to address these issues in practice. Additional specific responsivity issues that have received attention include mental health functioning; psychosocial functioning, such as housing stability and economic stability, which could impact availability and receptivity to treatment; and the geographical location of participants' residences.

At the center of the Specific Responsivity principle is the question of how correctional programs can be tailored to support and, if possible, accelerate an individual's ability to benefit from the interventions he or she is receiving. As such, in order to maximize participants' engagement in and benefit from interventions, the Responsivity principle focuses on how interventions can be adapted or tailored to support participants' motivation level and commitment to the intervention.

Examples of the Specific Responsivity Principle in Action

Research on approaches to tailoring correctional programming to address specific responsivity issues is in their early stages. Mental illness is one specific responsivity issue that is receiving attention because people with mental illness are involved in the criminal justice system at twice the rates of people without mental illness, and once involved, recidivate more often and more quickly than any other group. Mental illness is thought to represent a specific responsivity issue in correctional programming because the neurocognitive and social impairments associated with mental illness can impede individuals' ability to participate in and benefit from correctional programming. Specific neurocognitive issues that require consideration include participants' speed of learning, capacity to sustain attention, and ability to retain and recall information. Specific social impairments that require consideration include the participants' ability to accurately recognize emotions; ability to interpret emotions in others; and ability to effectively identify, interpret, and respond to social cues.

One example of how correctional programming has been adapted to meet the specific needs of people with mental illness is the development of a targeted service delivery approach. This approach tailors correctional interventions to the specific

needs of people with mental illness by engaging additional therapeutic strategies during the delivery of correctional interventions that are designed to maximize an individual's ability to participate in and benefit from the intervention materials. The therapeutic strategies used in this approach include repetition and frequent summaries, active coaching, low-demand practice, amplification techniques, and incentives for participation. Research on the effectiveness of approaches such as this is in an early phase, so no information is available on whether approaches such as the one described here improve outcomes for people with mental illness involved in the criminal justice system. But due to the pervasive involvement of people with mental illness in the criminal justice system, more research is expected to take place in the coming years.

Future Directions

The Responsivity principle provides the field of correctional rehabilitation direction on the most effective way to address criminogenic needs among offenders with high risk of recidivism. The conclusions that the General Responsivity principle draws about the most effective types of interventions for justice-involved populations are rather straightforward and draw from a robust body of research. The field has seen a rise in specific responsivity issues that could help to maximize the impact of correctional interventions with specific populations. However, as the range of potential responsivity increases, research needs to identify the responsivity issues that have the greatest potential to improve correctional programs, and then methods to address these responsivity issues need to be developed and tested.

RESTITUTION

Restitution refers to a judge's sentencing decision ordering a convicted offender to compensate the crime victim for financial losses incurred because of the crime. The primary basis for restitution is that a wrongdoer should make the victim whole by providing resources (most often money) to put

the victim in the same position he or she was in before the crime occurred. Restitution stands in contrast to fines, which are economic sanctions imposed as punishment, and fees, which are economic sanctions imposed to reimburse the criminal justice system for the past costs of arrest and prosecution and future costs of supervision.

Restitution can be ordered for tangible losses that result from damage to or loss of property; from harm to a person resulting in medical, hospital, and pharmaceutical expenses; and from money losses and lost wages. Victims must document these losses through bills and receipts. Generally, restitution is not available for intangible losses (e.g., pain and suffering, reduced quality of life, fear of crime), for speculative losses, or for future damages. Victims could seek compensation for such losses through a civil suit for damages, but because most defendants have few assets and limited incomes, civil suits are generally impractical.

Restitution is widely supported because it is believed to help victims, offenders, and society. For the victim, aside from the compensatory aspect of the money, an order of restitution has symbolic value, in that the imposition of restitution is a public acknowledgment that the victim suffered a loss that should be compensated. Restitution can also help restore victims' self-worth and can provide a sense of fairness.

For offenders, the rehabilitation aspect of restitution is aimed at changing offenders' behavior by forcing them to recognize both the losses that they have caused and their responsibility for repairing those losses. Such recognition should promote reintegration into the community. That is, offenders should be more likely to seek employment and to maintain ties to the community. In addition, restitution has punishment aspects, in that the requirement of making payments is more onerous than straight probation. For society, because restitution can restore fairness to victims and can both punish and rehabilitate offenders, it can rebuild citizens' confidence in the criminal justice system. After reviewing the history of restitution, this entry focuses on restitution as a form of payment to victims and a form of rehabilitation for offenders and concludes with a brief discussion of areas for future research regarding restitution.

History

The idea of restitution is at least 4,000 years old, as several legal codes from the Middle East (e.g., the Code of Hammurabi [ca. 1700 BCE]) required restitution for property offenses and other codes required restitution for both property and violent offenses (e.g., the Code of Ur-Nammu [ca. 2050 BCE]). In the Bible, in Leviticus 6:1-5, there is an explicit recognition of the need for restitution: "If anyone sins and commits a breach of faith . . . through robbery, . . . he shall restore what he took by robbery . . . he shall restore it in full, and shall add a fifth to it, and give it to him to whom it belongs." Exodus 22 discusses restitution for theft. Roman law and Germanic tribal laws also included restitutionary sanctions.

In the Middle Ages, crime victims were compensated for their losses under a system according to which there was a preset rate for the type of harm that was done. For homicide, the amount depended on whether the victim was a noble or a serf. For injuries, the amount depended on the type of injury. As long as offenders paid the compensation they owed, they were protected by the king. However, if they did not pay the restitution they owed, they were considered to be outside the law, and victims could punish them without consequences. For administering this system, the king demanded a fee. By the 12th century, this fee had greatly increased, and payments to victims had dramatically decreased. The transition was completed in 1256, when King Louis IX of France ended restitution completely. During the next several hundred years, in addition to fines, kings added such sanctions as torture, banishment, and flogging.

In colonial America, victims were entitled to restitution. In colonial Massachusetts, for instance, thieves had to pay treble damages to victims, in addition to being whipped and standing at the gallows with a rope around their necks. If the thieves could not pay the restitution, they worked as an indentured servant for the victim or a third party. After 1785, when Massachusetts established its first prison, thieves were imprisoned and victims' losses were ignored, and by 1805, Massachusetts had completely eliminated treble damages to victims. For the next 170 years in the United States, prosecutors and judges gave little consideration to the concerns of crime victims in the prosecution and punishment of offenders.

The use of restitution was revived in the early part of the 20th century, when it was permitted as part of suspended sentences and probation. By the 1930s, 11 states had legislation permitting judges to order restitution as a condition of probation. Beginning with the 1967 report from the President's Commission on Law Enforcement and the Administration of Justice, there were consistent calls to require offenders to pay restitution to victims. In 1982, the President's Task Force on Victims of Crime recommended that judges order restitution to all victims who suffered financial loss.

At the federal level, restitution was established in 1982, following passage of the Victim and Witness Protection Act, and was made mandatory in almost all federal cases in 1996 following passage of the Mandatory Victim Restitution Act. All states have laws authorizing restitution, either as a condition of probation, an independent sentence, or both. In addition, 33 states make restitution mandatory, and 20 states give victims a constitutional right to restitution.

Restitution as Payment to Victims

Even though all states authorize restitution, other laws generally make it less likely that victims will receive restitution. For example, because most defendants have limited resources, the order in which economic sanctions are paid (i.e., whether restitution is paid before or after fines and fees) will largely determine whether the victim receives any restitution. Only eight states have laws that permit the seizure of property or assets or allow the garnishment of wages in order to satisfy the restitution order.

Even among these mandatory statutes, there is little consistency, since some states require restitution only for violent crimes, whereas others require restitution only for property crimes. There are also differences among the states in terms of who can receive restitution. In some states, only the victim can receive restitution, whereas in other states, family members and victims' estates as well as agencies that provide assistance to victims (e.g., victim service agencies, compensation programs) can receive restitution. There are also differences among states in terms of whether indirect victims (e.g., insurance companies) and local

governments are entitled to restitution. In some states, incarcerated offenders must pay restitution, whereas in others, offenders must be on probation or parole. States also differ in terms of whether or not juveniles are obligated to pay restitution.

Simply because there is statutory support for restitution does not necessarily mean that judges impose it when they are authorized by law to do so. Restitution is imposed in less than half of the cases for which it should be imposed, whereas fees imposed on offenders for the costs of criminal justice processes are imposed in more than half of the cases, a pattern that suggests judges believe it is more important for offenders to pay money to communities than to victims. Judges are more likely to order restitution for offenders who are more likely to pay, meaning that better educated and employed offenders are more likely to receive restitution orders. Even if the restitution is ordered by the court, most victims do not receive all of the restitution they are owed and many do not receive any of the restitution. Even if it is paid, however, the money does not go to the victims when they most need it, which is right after the crime occurs.

Across jurisdictions, restitution has been handled in one of four different ways, two of which are victim-focused (victim/witness assistance programs and victim-offender reconciliation programs) and two of which are offender-focused agencies (probation supervision and court-based employment programs). The Office for Victims of Crime, an agency within the Department of Justice, has been critical of many restitution programs because there is often ambiguity about who is responsible for monitoring, collecting, disbursing, and enforcing restitution payments.

Adult offenders are more likely to make payments if the amounts they owe are reasonable in light of their ability to pay, if they are tied to the community through employment, school, or tenure in the community, if they have less serious criminal histories, and if they are given enough time to pay. Compliance rates also seem to be higher when enforcement efforts are high. Offenders who do not pay the restitution they owe can be made to pay if they are threatened with jail and if the threat of probation revocation is real. But such incarcerations are expensive, sometimes costing more than the money owed. One study suggests a more cost-effective procedure: Offenders who

regularly receive information about what they have paid and what they still owe are more likely to pay their restitution.

Restitution as Rehabilitation

Aside from addressing the needs of victims, restitution is intended to rehabilitate offenders by making them understand that the victim was harmed, that they were responsible for causing that harm, and that they are responsible for making the victim whole. Based on the notion of reintegrative shaming, which favors procedures that focus on shaming the act rather than the offender, that encourage offenders to make amends for their crimes and that allow them to be reintegrated into the community, it is reasonable to expect that paying restitution would be associated with lower recidivism. Research suggests that is so. Studies indicate that successful completion of a restitution order is generally one of the strongest predictors of lowered recidivism. Such positive effects of restitution payment may be especially likely for individuals who are more integrated into the community (i.e., those who are older, married, and employed).

In recent years, many states have developed restitution centers, which are community-based residential and nonresidential programs designed to provide an alternative to incarceration or to serve as transitional placements between prison and the community. In these centers, participants usually receive support services of various types (e.g., substance abuse, education, vocational training). Importantly regarding restitution, participants are required to work and to provide payments to crime victims.

Future Research

There is a need for more research examining how individual factors about offenders and victims and how contextual factors about the community (e.g., poverty) and the criminal justice system (e.g., case loads, treatment availability) are related to the imposition of restitution. Because most victims do not understand the restitution process and do not believe they are kept informed about the restitution in their case, other research, within the framework of restorative justice, needs to examine how well restitution operates to restore victims psychologically as well as

financially and, as compared to other programs (e.g., community service), to make the offender accountable. Finally, work needs to be done on the extent to which informational support (e.g., about the operation of the criminal justice system), emotional support (e.g., concern evidenced by a victim/witness office), and procedural support (e.g., providing victims an opportunity to be heard at sentencing) can make up for the fact that restitution may not be imposed or, if imposed, not paid.

RESTORATIVE JUSTICE

An important movement in the field of criminal justice—as well as in the understanding of justice in general—is the restorative justice movement that gives voice and agency to victims, focuses on accountability by the offender, understands the importance of relationships and relational engagement (including the role of community), and works toward a justice that is healing. Such a movement is no doubt crucial to considerations of criminal psychology since it focuses on the psychological needs of victims as well as offenders. Conceptually speaking, offender behavior and consequences therein are inextricably linked with the pursuit of justice and the subjective emotional dimensions of such a pursuit. For victims and offenders, restorative justice provides a path to healing. Howard Zehr, the father of the modern restorative justice movement, defines restorative justice as a process involving individuals who have a direct stake in specific offenses undertaking the task of addressing harms, uncovering needs, and determining obligations in the quest toward achieving justice.

This understanding of justice is different in several ways from retributive justice, the primary approach widely implemented within the criminal justice system. Retributive justice is offender focused and asks whether a law has been broken and, if so, how the offender should be punished. Accountability is imposed through an adversarial system. Restorative justice, however, begins with victims and asks what the harm is and what needs to be done by the responsible parties to address the harm. Victims' specific stories and needs are heard, including the need itself to be heard, to receive answers, to have harm and needs addressed through restitution and accountability, and to experience the empowerment of participating in deciding what needs to be done to address the harm. In the criminal justice system, victims often feel victimized twice, once by the crime and again by the proceedings at trial, including cross-examination. This is because, in the criminal justice system, the state functions as the victim. The adversarial-retributive justice model informs more than the criminal justice system because its spirit has influenced the way conflicts are dealt with in most settings.

This entry defines restorative justice; discusses foundational values of relational and interpersonal healing, holistic dimensions of such an approach, and philosophical considerations; and provides a case example.

History and Aims

Restorative justice affirms accountability by asking the responsible party to do whatever can be done to accommodate or satisfy the victim(s) in the wake of the offense. Requiring offenders to take responsibility is not only key to their victims and communities but critical to the offender's own learning and healing. Prison is still a possibility for some but it no longer becomes the default consequence of the justice system. Within restorative justice, the offender begins to understand the harm done and addresses guilt and shame by taking responsibility, thereby working to make things right. The offender also has the opportunity to be seen in context (not just in terms of the crime committed), participate in the decision as to what needs to be done to move forward, and open the way to being reintegrated into community.

The needs and responsibilities of communities are also addressed in restorative justice models. It aims to address the need for safety, for example, supporting and assisting those harmed. It also aims to hold offenders accountable, while at the same time supporting, assisting, and reintegrating offenders back into community. Communities can examine the root causes for the crime and take responsibility for addressing those conditions. One key goal of restorative justice is to promote systemic healing and the transformative creation of community.

Unlike the adversarial process implicit within retributive justice, restorative justice allows for the parties themselves to engage each other to understand the harm and decide together the scope of accountability. This creates the possibility of empathy and recognition and trends toward the goal of a more direct and interactional form of apology and forgiveness. Ideally, this engagement occurs directly but, when necessary, can be done indirectly through letters, videos, or even a surrogate. This is a voluntary process that works toward consensus.

The modern movement began in earnest with Zehr's 1990 publication, *Changing Lenses*. Since then, restorative justice models have spread widely throughout the world. The movement is based on ancient traditions. For example, most aboriginal communities practiced something similar to what today is referred to as *restorative justice*. In the West, before the Normans took over community justice programs in the name of the state (thereby gaining greater power over its citizens), justice was understood in terms similar to restorative justice. Although biblical texts, such as the Hebrew Bible and the New Testament, contain retributive threads, the overall arc of their understanding of justice is consonant with restorative justice.

Development and Key Practices

Three major practices have emerged within the restorative justice movement. The first is victim-offender conferences that find similarities with the mediation movement. The person harmed (victim) meets with the responsible party (offender) to communicate the level and nature of harm and agree on the terms of the accountability. The process is led by a trained facilitator who works to prepare the victim and offender to work together. This process can involve only the direct parties, or it may expand to have others participate in secondary roles, with the focus remaining on the engagement of the victim and offender.

The second process, family group conference, originated in New Zealand and is deeply indebted to the Maori cultural way of dealing with harm. In 1989, the juvenile justice system of New Zealand was revolutionized so that the primary response to juvenile crime was the family group conference, with the court system as a backup. A key focus of the family group conference is to help and encourage young offenders to take responsibility for, and change, their behavior. Families play significant roles in working with the responsible party to determine what the accountability will be. The state is represented by a facilitator and the prosecuting police office. Victims have input, but the decision is primarily in the hands of the victim's family with the state representative making sure that consequences are realistic and acceptable within the bounds of broader civic responsibility.

The third process is the circle process that was inspired by Native American and First Nation practices (among others) of dealing with harm. The circle uses a talking piece that is passed around the circle so all voices are heard. The participants agree on the values that will guide their conversation. Circles often involve various people and can include family members, support people, and community members. This allows an opportunity for community members to address root causes together.

Restorative justice has also been applied to large-scale, geopolitical wrongdoing and criminal justice. Instead of using the adversarial-retributive justice system to address crimes such as violence against civilian groups or ethnic cleansing, nations are turning to the principles and practices of restorative justice, such as during the Nuremberg trials after World War II. Bishop Desmond Tutu emphasized the role of restorative justice in the context of the Truth and Reconciliation Commission in South Africa. The whole nation had the opportunity to listen to the victims' stories and out of this arose attempts at reparations. The truth telling led to a significant report including the testimonies. The nation also listened to offenders who were willing to tell the truth about their actions. Ongoing work toward making these sorts of governmental commissions more restorative, rather than retributive, continues today.

Finally, much has been written on restorative justice as a way of life that informs the way people deal with harm in all their relations and how to treat each other in a way that creates just and right relations.

Philosophical Considerations

One significant aspect of restorative justice is that it brings much needed concreteness and relationality to an oftentimes abstract and depersonalized form of criminal engagement. Western notions of morality and justice have tended to lack behavioral substance in that they are focused on theory rather than practice. It is key to acknowledge that notions of justice are, in fact, not notions at all. Rather, they are lived realities that demand embodied manifestation. As such, restorative justice can serve as an elegant corrective against unhelpful splitting (such as splitting victims from offenders, persons from

contexts, and ideas of justice from just actions) and can help promote physical reconciliation between those involved in events of criminal harm. Long-standing dualistic and abstract philosophical legacies have steered contemporary approaches to justice into realms that divert attention away from transformation and toward punishment.

Case Example

In order to better understand what restorative justice might actually exhibit, a hypothetical case example is provided here.

Martin is a 15-year-old boy who comes from a lower than average socioeconomic bracket. He is an only child and lives alone with his mother, who works full time. His father has been absent since before Martin's birth. From an early age, he struggled to make friends, perform well in school, and find ways to productively deal with feelings of anger and isolation. By the time he reached his teenage years, Martin had developed a habit of expressing his inner turmoil by vandalizing property in and near his neighborhood.

One evening, Martin threw a stone through the window of a home several blocks away from his. Several nearby neighbors witnessed this and were able to identify Martin to the police who were investigating. The homeowner of the vandalized property was 81-year-old Stella. Stella had been living alone for 8 years since her husband passed away. She never had children and had become so distraught since losing her husband that she rarely left home. She was asleep on her couch when the stone came through her window. She was terrified and could not sleep comfortably for days after. The police indicated to Stella that she could decide to pursue traditional means that would deliver punishment to Martin for his crime. They also indicated to her that they could let Stella decide how to proceed since Martin was a minor with no prior record. Stella decided that she wanted to speak with Martin and his mother.

Upon doing so, she was immediately struck by how young, confused, and aimless Martin seemed. He was hardly the criminal she expected based on her sleepless nights in the wake of the crime. Martin, too, was impacted by the meeting. He immediately came to see that Stella was frightened by what he had done. For the first time, he put a human to the receiving end of his destructive

behavior. He cried uncontrollably and asked for Stella's forgiveness. Martin's mother assured Stella that he would be dealt with appropriately if she would spare them the difficulty of having charges pressed against Martin. Stella indicated that she would agree not to press charges if Martin would come rake the leaves in her front yard three times a week for a month. The agreement was made, and the police discontinued their involvement.

Martin held up his end of the agreement and, by the end of the month, had made his first real friend in Stella. Stella had grown quite fond of Martin as well and began to make him lemonade while he worked under the hot sun. She told him stories about her husband, and he told her stories about growing up without a father. Martin regretted his actions and yet had done so without being punished in the retributive sense.

RESTORATIVE POLICING

Restorative policing is a service-oriented style of policing in which police officers are viewed as peacemakers who focus on relationship building and engagement with the community, rather than solely collaboration with and cooperation from the community. Restorative policing recognizes that officer safety will be enhanced through approaching dangerous situations with restorative values such as respect. Arguably, one of the long-term goals of law enforcement is to motivate law violators to become more self-regulating of future criminal behavior and respectful community citizens. However, this goal is often neglected in traditional models of policing that are based on a reactive, quasi-militaristic approach grounded in a use-of-force culture. In the 21st century, policing ideology appears to favor a more proactive and service-oriented approach than the traditional models of policing.

The service-oriented policing ideology is not new and can be attributed to Robert Peel, who encouraged a similar policing style as early as 1829, when policing was attempting to develop a professional identity. In the 1980s and 1990s, various terms were introduced to capture the more service-oriented style of policing, including *problem-oriented policing*, *community policing*, and *restorative policing*. The unifying thread connecting each of these approaches is that the community has a central role in how crime is managed. However, this concept has met with resistance because of different viewpoints about the power police officers need to maintain to ensure officer safety. Specifically, restorative policing has been challenged because of its distinct perspective on managing criminal behavior.

Although these various styles of service-oriented policing are similar, restorative policing differentiates itself because it does not maintain the traditional police psychological mindset, which upholds the dichotomy between offender and victim. Traditionally, the offender is viewed through a lens of us versus them and not as an important member of the larger community. Oppositely, restorative policing uses a mindset in which crime is viewed as a violation of a relationship, and the offender has the obligation to repair the harm experienced

by the victim and the community. Restorative policing is grounded in values such as compassion, integrity, transparency, respect, and fair process. Police legitimacy is built using strategies and tactics that are consensual, transparent, and accessible to all community members. It is not based on one particular practice or method; rather, it is a change in the paradigm of how individuals respond to crime and the harm it causes.

The restorative policing model is based on interpersonal and communication skills rather than solely on analytical skills identifying solutions to specific problems. Although the community policing model has a goal of preventing and managing crime using a nonreactive/control-oriented approach to crime, it does not focus on the reparation of the harm caused by the offender to the victim and the community. The restorative focus has caused tension in traditional policing environments because it requires a sharing of power, which tends to elicit a fear for officer safety. However, advocates have argued that when restorative policing utilizes a range of police tactics and strategies reflective of local communities' norms and when implemented correctly, it can prevent crime and help offenders accept responsibility for and repair the harm caused by their actions.

Moreover, advocates of restorative policing contend that conflict in communities can be reduced by increasing victims' and communities' confidence in responding to crime through being included in the process of finding the solutions needed to repair the harm caused by the criminal behavior. Furthermore, they assert that restorative policing can increase police officer job satisfaction, enhance officer safety and emotional well-being, and decrease the use of force when responding to crime. Further research is needed to empirically examine these assertions.

If restorative policing is to achieve legitimacy, it requires the community at large to embrace a set of values recognizing the inherent worth of all members of the larger society including offenders. Researchers have proposed a framework for implementation, which includes the following:

1. Cultivate support for restorative policing from the top-down. Identify ways to implement innovation and leadership at all levels of

organizational structure. However, preparation for a shift in a top-down hierarchical structure should be gradual and planned.

2. Cultivate support for restorative policing from the bottom-up. Engage and empower frontline officers at the microlevel to strengthen linkages grounded in restorative values between the police and the community, including individuals at risk of involvement with the law. A message delivered by frontline officers in which police work is viewed as being about the promotion of victim and community empowerment and emotional well-being in contrast to just a sole focus on arresting the offender will be important. Such a balanced view of police work expands the frontline police officer's public servant role to encompass all stakeholders in the justice system.
3. Work to operationalize on a local level what restorative policing strategies and tactics look like and the anticipated expected outcomes. Engage a university partner to conduct research.
4. Engage police officers and the community in training on the restorative policing model. Develop a sustainable and comprehensive training program. Training should connect restorative policing to other models of policing but explicitly define the differences. Officers who embrace the restorative policing approach should be involved in the training of other officers so that trainees can learn what to expect about using the restorative policing model from officers who have actual experience with the model.

Restorative policing holds great promise at a time when the need to increase police legitimacy is strong, and developed nations have recognized the failure of the punitive *get tough on crime* approach to crime management. The implementation of the paradigm shift to a restorative policing model requires an interdisciplinary approach including but not limited to psychologists, criminologists, law enforcement, and the community at large if it is to be successful. Currently, a great deal of room exists for research examining the benefits and weakness of the restorative policing model.

RISK ASSESSMENT, ACTUARIAL

Actuarial risk assessment measures consist of a set of predetermined risk factors (sometimes statistically weighted) that are combined based on an algorithm, which produces a total score that is associated with a final risk estimate or probabilistic statement regarding the likelihood of future recidivism. When assessing risk of general and sexual violence, two commonly used actuarial risk assessment measures are the Violence Risk Appraisal Guide (VRAG) and the Static-99, respectively. Although there has been extensive development and validation of actuarial measures with adult offender populations, there has been limited uptake of purely actuarial measures among young offenders with measures such as the Youth Level of Service/Case Management Inventory representing an adjusted actuarial approach (i.e., lacking in the probabilistic estimate of risk).

This entry begins by explaining the development of actuarial risk assessment. Next, it describes the strengths and criticisms of actuarial risk assessment. The entry then discusses the use of actuarial risk assessment within a risk management/treatment paradigm and concludes with a brief discussion of future directions.

Development

While the initial selection of risk factors for consideration in an actuarial measure can be informed by the broader empirical literature (e.g., meta-analysis), final selection of the risk factors is typically based on their association with an outcome

of interest within a development sample (e.g., violent recidivism) and their incremental contribution relative to the other risk factors in predicting outcome. Thus, actuarial measures represent an empirical approach to the risk assessment process. This is not to say, however, that all actuarial measures are void of psychological or behavioral theory. For instance, development of the Level of Service Inventory–Revised, an actuarial risk measure designed for assessing risk of general recidivism, was grounded within the Risk-Need-Responsivity principles and psychology of criminal conduct as developed by psychologist Don Andrews and his colleagues.

Strengths of Actuarial Risk Assessment

Actuarial risk assessment has consistently outperformed unstructured clinical judgment in predicting short- and long-term violent and sexual recidivism with predictive accuracy that is significantly better than chance. To date, several meta-analytic investigations have found actuarial risk assessment measures to be significant predictors of various forms of outcome such as violence, sexual violence, and general recidivism. Although the majority of the recidivism research has not focused on the nature and severity of violence, there is preliminary evidence to suggest that actuarial measures are significantly associated with such outcomes. This is not surprising, since several of the measure developers have pointed out that actuarial measures were designed to predict these types of outcomes.

Unlike clinical judgment, actuarial risk assessment is systematic, impartial, and transparent. Research conducted within applied settings has revealed moderate to high interrater agreement between raters and, in a few instances, between clinicians and researchers (e.g., the Static-99). Likewise, the predictive validity of actuarial risk assessment is similar whether it is scored within an applied (i.e., clinical) or research setting. Similarly, moderate to high predictive accuracy has been found when actuarial measures are scored by frontline staff (e.g., police and parole officers). This highlights an appealing aspect of actuarial risk assessment in that extensive clinical training is not required for optimal predictive accuracy to be achieved.

Although some may view the lower level of training required (e.g., 1-day workshop) for some actuarial risk measures as a potential limitation, there are several instances in which this is preferable. One example is the Ontario Domestic Assault Risk Assessment (ODARA), a 13-item actuarial risk assessment measure designed for use by police officers and frontline police personnel to predict male-to-female intimate partner violence recidivism. Police officers investigating incidents of intimate partner violence are often faced with situations in which quick decision-making is key. Such decisions may be related to whether the perpetrator should be released or detained following an incident of intimate partner violence (i.e., bail hearings). Actuarial measures such as the ODARA are ideal in situations where the ODARA was specifically designed to be administered quickly using information available to police officers (e.g., criminal record, victim interview). Moreover, with actuarial measures such as the ODARA, the provision of a final risk estimate further allows for easier interpretation of the results. Lastly, given the shorter administration time and lower requirements regarding education and training, actuarial measures such as the ODARA can be more cost-effective, without compromising predictive validity, relative to other in-depth psychologically based risk assessment measures, particularly when being administered by frontline personnel.

Criticisms of Actuarial Risk Assessment

Historically, given that the selection of risk factors is based on their association with an outcome of interest, actuarial risk assessment measures have predominantly comprised static risk factors or historical variables given their robust associations with outcome. Static risk factors remain relatively stable over time and are not amenable to treatment (e.g., criminal history variables such as age at first offense). This is problematic because the violence risk assessment process has moved away from a purely predictive model to a risk management model. Thus, the overreliance of some actuarial measures on static risk factors has limited their usefulness within a risk management/treatment paradigm. Granted, while an actuarial risk assessment measure comprising solely static risk factors may be of assistance in identifying who is

at higher risk to reoffend, there remains a need to assess treatment targets (i.e., criminogenic needs or dynamic risk factors).

There are other important concerns that arise due to the procedures used for item selection. First, the number of risk factors may be limited and may ignore other risk factors that are equally important but whose validity is unknown (i.e., factors that were not coded within the development sample). Likewise, the weighting procedures, such as those associated with the VRAG, have led to criticisms regarding the appropriateness of items both on legal and ethical grounds. For instance, having a female victim and increased severity of victim injury were weighted negatively on the VRAG. In contrast, having a male victim and no victim contact resulted in a positive weighting. More recently, with the revision of the VRAG, items such as victim injury and female victim have been removed.

Another criticism of actuarial risk assessment is the issue of generalizability of the final risk estimates or absolute recidivism rates (referred to as *calibration*). A meta-analytic examination of the absolute recidivism rates of the Static-99 (and its variants) found significant variation across samples. This highlights the need for recalibration of the absolute recidivism rates when an actuarial measure is applied to a population that lies outside that of the development sample. Similarly, with the passage of time, rates in the population will fluctuate and legislative changes may alter what constitutes a violent act. As such, the absolute recidivism rates must be adjusted accordingly to ensure that the actuarial measure is up-to-date; however, it is the responsibility of the assessor to determine whether or not an actuarial risk assessment measure is an appropriate fit for the client being assessed. In addition, some researchers have argued that the need for recalibration is not a criticism per se; rather, it is a necessary condition of good science.

To date, of all the criticisms that have been leveled against actuarial risk assessment, none have been as controversial as the argument that absolute recidivism rates derived from group data cannot be applied to the individual. However, despite these claims being refuted on statistical grounds, this criticism has advocates within the literature. This has, in part, led to the development and use

of other metrics to communicate actuarial risk (e.g., percentile ranks, risk ratios).

Moving Beyond a Purely Actuarial Approach

With the advancement in assessment technologies and the development of several actuarially based risk assessment measures, describing these measures against a purely actuarial framework is no longer sufficient. Jeremy Mills and his colleagues offer examples of actuarial risk assessment, which fit well within a risk management/treatment paradigm: *integrated-actuarial risk assessment* and *dynamic-actuarial risk assessment*.

Integrated-Actuarial Risk Assessment

The integrated-actuarial approach is a form of actuarial risk assessment that incorporates actuarial risk estimates (AREs), potentially dynamic risk factors, intervention/treatment recommendations, and risk management strategies. This form of actuarial risk assessment is exemplified by the Two-Tiered Violence Risk Estimates, which represents a two-tiered approach to risk assessment. Embedded within the measure are the ARE that comprises 10 items (e.g., childhood antisocial behavior, prior incarcerations) and the Risk Management Indicators that assess 13 areas of functioning that have been empirically linked with violence (e.g., employment status, family instability). The Risk Management Indicators, which is an aid in explaining the underlying risk level, is designed to identify areas in need of risk management and to monitor potential changes in risk. Measures such as the Two-Tiered Violence Risk Estimates eliminate the need for multiple risk assessment measures and overcome many of the criticisms concerning purely actuarial risk assessment while allowing for the assessment to be anchored by the ARE.

Dynamic-Actuarial Risk Assessment

The dynamic-actuarial approach is similar to the integrated-actuarial approach in that it incorporates AREs and potentially dynamic risk factors; however, within the dynamic-actuarial approach, the reassessment of dynamic risk has

the potential to alter the underlying ARE. An example of this form of actuarial risk assessment is *The Dynamic Supervision Project* that incorporates the Static-99, Stable-2007, and Acute-2007. Within this framework, changes in dynamic risk on the Stable-2007 can alter the risk level of the Static-99, and changes on the Acute-2007 can impact the combined Static-99/Stable-2007 risk level. These changes can lead to differences in absolute recidivism rates across multiple assessments.

Future Directions

Actuarial risk assessment remains an integral component of the risk assessment process. Because criticisms are associated with purely actuarial risk assessments, in combination with advances in risk assessment technologies, the area has made considerable gains that have resulted in the development of integrated- and dynamic-actuarial approaches.

RISK MATRIX 2000

Of the various approaches used in sexual offender risk assessment (unstructured clinical judgment, actuarial risk assessment instruments [ARAIs], and structured professional judgment), ARAIs outperform all other methodologies. Of the numerous sexual offender ARAIs currently available, the Risk Matrix 2000 (RM2000) is one of the most widely used and researched and is the focus of this entry.

Description

The RM2000 is probably the most frequently used second-generation ARAIs in the United Kingdom. In developing the scale, researchers created a two-dimensional risk assessment system for sex offenders referred to collectively as *RM2000*. The revised system has two scales, one for measuring risk of sexual recidivism—Risk Matrix 2000/Sexual (RM2000/S)—and one for measuring risk of nonsexual violent recidivism—Risk Matrix 2000/Violent (RM2000/V) in sexual offenders.

The RM2000/S and RM2000/V scales were constructed to yield four summary risk categories: low, medium, high, and very high. The scores of both scales can be combined to give a composite risk of reconviction for sexual or nonsexual assault—Risk Matrix 2000/Combined. In developing the RM2000 scales, the authors referred to a landmark meta-analysis of sexual reoffending predictors as they felt this study offered a more complete guide to the literature, containing more precise and representative estimates of the

predictive accuracy of individual factors than would be obtained from any individual study.

The RM2000/S uses a two-step system to risk assessment. Step 1 contains three risk items (number of previous sexual appearances, number of criminal appearances, and age divided into three age bands), the sum of which is translated into a risk category. Step 2 considers four aggravating risk factors (any conviction for sexual offense against a male, any conviction for a sexual offense against a stranger, any conviction for a noncontact sex offense, and single-never been married); the presence of two or four aggravating factors raises the risk category by one or two levels, respectively.

The RM2000 can only be used if the offender meets the following tests:

1. The offender must be aged 18 years or over.
2. The offender must have at least one conviction for a sexual offense committed when the offender was aged 16 years or over.
3. The offender must be male.

All appearances for sexual offenses are counted when scoring RM2000/S, including ones where the offender was under the age of 16 years. The scale can also be used in cases where an individual has been charged with a sexual offense but not yet convicted.

The scale has demonstrated good interrater reliability with an absolute agreement for a single rating of 0.90 (which is considered *excellent*) across 50 cases. The item with the lowest reliability was the *noncontact* item, which still had good interrater reliability (93.2% agreement). Agreement for the risk category rating is also good (94.9% agreement).

Predictive Accuracy

Since the 2003 development study, the scale has been independently validated by several research studies using samples in Scotland, Denmark, England and Wales, Canada, and the United States. In the development study, the research group examined the predictive accuracy of the RM2000/S on a treated and an untreated sexual offender sample using the area under the curve (AUC), which is a measure of prediction accuracy

ranging from 0 to 1.0; values of 0.56, 0.64, and 0.71 represent small, medium, and large prediction effects, respectively. The RM2000/S yielded good accuracy in predicting sexual reconviction (AUC = 0.77 treated sample, and AUC = 0.75 untreated sample), and the RM2000/V obtained higher validity indices (AUC > 0.78) in predicting of nonsexual violent reconviction in different long-term samples. Conducting a series of cross-validation studies with different England and Wales samples elsewhere reported varying results for the predictive accuracy of the RM2000 scales. On the one hand, the tools yielded impressive validity indices up to AUC = 0.86 for the prediction of violence including sexual recidivism by the RM2000/V. On the other hand, the predictive accuracy was hardly better than chance (AUC = 0.56).

A further validation study was completed using the RM2000 on a Scottish sample of sexual offenders compared against a sample from England and Wales. Of the 771 sexual offenders, 116 (15.0%) were reconvicted of a sexual offense at any time following their release from prison, while 83 (10.8%) were reconvicted of a sexual crime within 5 years of their prison release. This compares with a 19.6% 5-year sexual reconviction rate for the 1979 England and Wales cohort. The predictive accuracy of the RM2000/S in the Scottish sample was AUC = 0.73 compared with an AUC of 0.75 in the England and Wales 1979 sample.

In 2010, another research group examined the predictive accuracy of the RM2000 scales on a large sample of 9,824, of which 4,946 sexual offenders were followed up at 2 years and 578 followed up at 4 years. The predictive validity of the scale was explored for different subgroups of sexual offenders. The higher risk groups offended more quickly and at a higher rate than lower risk groups. The RM2000/S obtained moderate results (AUC = 0.68) in predicting sexual reconviction, whereas the RM2000/V obtained good results in predicting nonsexual violent reconviction (AUC = 0.80).

As a subsequent evaluation of nine ARAIs on a sample of 590 sexual offenders in Massachusetts followed up over a 15-year period, the RM2000/S scale performed reasonably (AUC = 0.68) in predicting sexual reconviction. Compared to the other scales in the study, the RM2000 scales were

outperformed by the STATIC-99, a brief actuarial tool. Incidentally, the RM2000/V (AUC = 0.71) obtained the highest score across all nine scales in predicting violent reconviction.

In a 2013 meta-analysis, the findings were integrated from 16 unique samples (derived from 14 studies), which have examined the ability of the RM2000 to discriminate between recidivists and nonrecidivists. All three RM2000 scales provided significant predictive power for all recidivism types that were investigated (i.e., sexual, nonsexual violent, any violent, nonviolent, and any recidivism). The RM2000/S yielded the best predictive accuracy for sexual recidivism (Cohen's $d = 0.74$, considered large). The RM2000/V and the Risk Matrix 2000/Combined predicted nonsexual violent recidivism and any violent recidivism with similarly large effect sizes. The effect sizes were significantly higher using samples from the United Kingdom compared to studies with samples from other countries. The RM2000/S demonstrated moderate to large predictive accuracy among sex offenders, and the RM2000/V and Risk Matrix 2000/Combined are similarly effective for both types of violent recidivism as well as nonviolent and any recidivism. However, the authors noted that the predictive accuracy was quite low in sexual offender samples preselected as high risk or high need.

More recently, in a study examining the relationship between psychometric changes in treatment and recidivism in a sample of 3,773 sex offenders, the RM2000/S was used to establish a baseline of risk. Of the 3,027 offenders who had been released for at least 2 years, 1.7% had reoffended sexually to 4.4% who were reconvicted for sexual and violent offenses combined. Due to limitations in the study data, it was not possible to score two items: intimate relationship and stranger items of RM2000/S, so they used a modified RM2000/S. Since the modified RM2000/S scoring may have resulted in an underestimate of risk, those who were scored as having any aggravating factors were raised a risk category. The authors compared the modified version against a subsample (about half of the total cases) for whom full RM2000/S scores were available and found that approximately 64% of these were in the same risk category, 9% were rated as a higher risk category, and 27% were rated as a lower risk category. This

indicated that the modified scoring procedure appeared to result in a greater level of underscoring than overscoring. Using the modified version, the RM2000/S obtained moderate results (AUC = 0.64).

Applying the RM2000/S to Child Molesters and Rapists

A 2011 study followed 275 sexual offenders ($n = 199$ child molesters; $n = 76$ rapists) over a period of 9 years and 2 months as part of an evaluation of a community-based sexual offender treatment program. For the child molester sample, there is a fairly robust relationship between increased risk level and increased rate of reoffending, with the medium-high categories having a significantly higher failure rate. However, the RM2000/S did not perform well with rapists (AUC = 0.64) compared to child molesters (AUC = 0.71).

The RM2000/S fared better in a Danish sample of 160 rapists and 144 child molesters, followed up over an average of 14.8 years, obtaining moderate results for sexual (AUC = 0.71) and nonsexual violence reconviction (AUC = 0.70).

Combining Static and Dynamic Frameworks

A 2015 study investigated the incremental validity of combining the RM2000 scales with the STABLE-2007 (a dynamic actuarial risk scale) on a Canadian sample of 710 sexual offenders (mean follow-up of 7.7 years). The RM2000/S obtained moderate predictive accuracy (AUC = 0.69) for sexual recidivism compared to the RM2000/V (AUC = 0.63), which performed better in predicting nonsexual violence (AUC = 0.74). The RM2000/S had a larger incremental effect over the STABLE-2007 than vice versus.

Special Populations

Sexual Offenders With Intellectual Developmental Disabilities (IDD)

Researchers in this field have noted that sexual offenders with IDD (IQ below 69) would have been rare in the original research samples, but offenders with IQs between 70 and 80 should

have been present in the original samples in reasonable numbers.

A number of studies have examined the utility of the scale in a sample of sexual offenders with IDD with moderate results. The predictive accuracy of the RM2000/S and the RM2000/V scales were compared against other scales with a mixed group of 212 violent and sexual offenders with IDD in England and Wales (mean IQ = 66), across three different levels of security. After a 12-month follow-up period, both the RM2000/V and RM2000/S AUCs did not attain significance for violent (AUC = 0.62) and sexual incidents (AUC = 0.61), respectively.

A 2011 study compared the Rapid Risk Assessment for Sexual Offense Recidivism (RRASOR), the Sexual Violence Risk-20 (a 20-item structured professional judgment sexual violence risk tool), the RM2000-V, and the Assessment of Risk Manageability for Intellectually Disabled Individuals Who Offend-Sexually-Stable and -Acute dynamic client subscales on a sample of 88 offenders: 44 mainstream and 44 sexual offenders with special needs (mean IQ = 69). The mean length in treatment was 18 months with a mean follow-up period of 109 months. While the sexual reconviction predictive validities of the RRASOR (AUC = 0.53) and the RM2000-V (AUC = 0.50) were little better than chance, the Assessment of Risk Manageability for Intellectually Disabled Individuals Who Offend-Stable (AUC = 0.60) and Assessment of Risk Manageability for Intellectually Disabled Individuals Who Offend-Acute, (AUC = 0.73) performed better. It should be noted that the RM2000/V is generally better at predicting violent reconviction than sexual reconviction.

A further study examined the predictive accuracy of the STATIC-99, RRASOR, and the RM2000/S in a sample of 27 sexual offenders with IDD in England and Wales followed up over a 76-month period. The STATIC-99 (AUC = 0.64) outperformed the RM2000/S (AUC = 0.58) and the RRASOR (AUC = 0.42). These results suggest caution when using the RM2000 scales with sexual offenders with IDD.

Internet Sexual Offenders

Offenders who have only been convicted of Internet offenses would not have been present in

the original development RM2000 samples. However, in the development sample, the RM2000 was tested on a sample of adult males with a history of being convicted for Internet sex offenses and attained an AUC that is comparable to what it has in regular samples. Like most ARAIs, the RM2000/S does not discriminate among individuals whose only known criminal behavior is downloading indecent images of children as these groups typically score low on such scales and have a low sexual recidivism rate. Individuals with Internet-only offenses would meet the scoring criteria for *noncontact* offenses. However, a key issue is whether these offenses were a prelude to a contact offense.

Of the few studies validating the scale on Internet sexual offenders, the predictive accuracy of a modified version of the RM2000/S was examined in a sample of 1,344 Internet sexual offenders. The overall rates of sexual reoffending were very low at 2.1% at 1-year follow-up, which increased to just 3.1% at the 2-year follow-up stage. At the 2-year follow-up, 74% (23/31) of the offenders were reconvicted of Internet-related offenses, 19% (6/31) were reconvicted of non-Internet offenses. The RM2000/S obtained moderate results in predicting reoffending (AUC = 0.67).

Conclusions

A number of cross-validation and meta-analytical studies have demonstrated the psychometric properties and predictive utility of the RM2000 scales. Compared with other ARAIs, the RM2000/S demonstrates moderate to large predictive accuracy among contact sex offenders (rapists and child molesters) and Internet sexual offenders although the predictive accuracy of the scale reduces slightly when applied to sexual offenders with IDD. Nevertheless, the RM2000/S can be used with confidence in assessing future risk of sexual reconviction in sexual offenders.

RISK PRINCIPLE

Robert Martinson wrote an article in 1974 which led to a *nothing works* doctrine with regard to offender rehabilitation. Since this time, a large body of literature has accrued aimed at discovering what does work in reducing the likelihood of recidivism among a criminal justice population. Much from this body of research can be synthesized into three core principles—the Risk-Need-Responsivity (RNR) principles. This entry focuses on the risk principle. The risk principle helps correctional entities to decipher how to match offenders to the appropriate level of correctional intervention, suggesting that intensive correctional supervision and treatment services be reserved for those offenders who are at higher risk of recidivism. This entry provides an explanation of the risk principle, examines how correctional programs have applied and implemented this principle, and explores what happens when it is ignored.

Principles of Effective Intervention

Like most systems, the field of corrections has limited resources to manage and treat those who engage in law-violating behaviors. Hence, knowledge about how to best spend those resources is crucial. A group of Canadians, led by Don Andrews, Paul Gendreau, and James Bonta, were at the forefront of research on effective correctional interventions. From their research emerged a body of literature that has been recognized as the principles of effective intervention. These principles, RNR, help guide decision-making for correctional policy makers and practitioners. Briefly described, the *risk principle* focuses on who to place in correctional interventions, the *need principle* suggests what offender needs should be targeted in order to reduce recidivism, and the *responsivity principle* provides guidelines as to how to treat an offender population with regard to the therapeutic model best suited for the population as well as how to address individual learning styles and barriers to success. Adherence to the RNR model has been associated with improved program outcomes as well as improved management of an offender population.

The risk principle, or the who principle, attempts to match the offender with the appropriate level of intervention based on risk. Thus, risk of recidivism is used to help determine who to place in various correctional interventions. Getting the right people in the right program has a significant impact on the effectiveness of a correctional intervention. Not considering risk when assigning offenders to programs can have harmful effects on the offender and the community.

Identifying Risk

In order to match offenders to services based on risk, one must be able to accurately ascertain the risk level of the offender. *Risk* refers to that individual's likelihood to recidivate; *risk level* or *risk classification* categorizes offenders into groups with a similar likelihood of reoffending. Often, these classification levels are described as low, moderate, high, or some combination thereof (e.g., low-moderate, high-moderate).

The literature suggests that use of clinical judgment to determine whether someone is likely to recidivate is not an accurate way to assess risk.

Rather, use of a validated, actuarial risk assessment tool is considered as best practice. There are many instruments designed to assess risk of general criminal recidivism. Examples of just a few common risk assessment tools include the Level of Service Inventory, developed by Andrews and Bonta; the Correctional Offender Management Profiling for Alternative Sanctions Risk and Need Assessment System, developed by Northpointe; and the Ohio Risk Assessment System, developed by the University of Cincinnati.

Assessments such as these include a range of static and dynamic risk factors predictive of offender recidivism. Examples of items one might find on a risk assessment include number of prior convictions or whether the individual ever had an alcohol or drug problem. Such instruments also include dynamic risk factors such as one's criminal associates, current drug use, current employment problems, or housing in high-crime areas. It is the composite risk score that allows for classification into risk categories. Once the risk level is known, this information can be used to match the offender to the appropriate level of intervention.

It is important to note that offense seriousness is often not correlated to likelihood of recidivism or risk level. For example, although homicide is arguably the most serious crime, many individuals convicted of murder or manslaughter do not pose a high risk of recidivism. Often, crimes such as these are crimes of passion or are situational to that specific case. On the other hand, less serious crimes such as theft or drug possession may be committed by a person with a lengthy criminal record and many criminogenic needs who is a high risk of recidivism. The focus of the risk principle is on identifying who is most likely to recidivate and applying programming and services to those individuals, rather than focusing on the seriousness of the crime committed.

Level of Intervention

In the field of corrections, there is a wide range of interventions to which an offender may be mandated. Some correctional interventions are low intensity and place limited demands on the offender. Other interventions are high intensity. These tend to be more intrusive and disruptive of the offender's current lifestyle; they also tend to

target a wider range of risk factors. With regard to treatment interventions, a low-level intervention might be considered a diversion program or a short-term education program (e.g., 3-day drug education program). A moderate-level intervention might consist of mandated intensive outpatient substance abuse treatment or a community-based anger management or domestic violence program (e.g., a community-based program lasting 4–6 months). An example of intensive treatment intervention would be a 6-month residential drug treatment program.

Correctional interventions are not only treatment based. There are also supervision- or surveillance-based interventions designed to monitor the whereabouts of offenders. Examples of these include traditional probation or parole, intensive probation caseloads, use of electronic monitoring devices, or even use of jails or prisons. These supervision-based interventions also have a continuum of intensity ranging from limited community monitoring to secure confinement. Finally, there are interventions that merge both treatment and supervision, such as specialty courts (e.g. drug, mental health, or reentry courts), whereby intensive judicial oversight is partnered with treatment services overseen by the court. Other combined interventions include specialized probation caseloads, such as an intensive mental health caseload where officers oversee probationers with mental illness and collaborate with mental health treatment providers.

With regard to the risk principle, the intensity of the intervention should match the risk level of the offender. Hence, more intensive interventions, such as residential programs, should be reserved for moderate- to high-risk offenders. Lower level interventions, such as a diversion program or non-reporting probation, are more appropriate for offenders who do not pose a high risk of future criminal behavior.

Costs of Ignoring the Risk Principle

Research suggests that when low-risk individuals are placed in intensive correctional programs, not only do these programs fail to reduce that individual's likelihood of recidivism, but participation in such interventions can actually increase that person's propensity to engage in crime. What this suggests is that programs designed to treat offenders

actually make offenders worse when offenders are not placed in the appropriate level of service.

When exploring why this might occur, it is important to consider the following. Individuals classified as low risk of recidivism by definition are more prosocial, meaning they are more likely to hold jobs, have a secure family or support system, have a network of law-abiding peers and associates, have limited problems related to substance abuse, live in stable neighborhoods, have good problem-solving and coping skills, and have prosocial attitudes and belief systems. Thus, mandating an intensive correctional intervention can disrupt those areas that shield the individual from developing a criminal behavior pattern. Furthermore, intensive correctional programs often serve higher risk individuals. When low-risk individuals are integrated into these environments, social learning ensues, and the low-risk individual begins to adopt some of the criminal thinking and behaviors of his or her higher risk peers.

In summary, exposure of low-risk individuals to high-intensity correctional interventions both disrupts protective factors and exposes those individuals to high-risk models of criminal behavior. Hence, the same intervention applied to a high-risk and low-risk individual can improve outcomes for the high-risk person, yet increase criminal involvement for the low-risk person. This is why, irrespective of the type of intervention being provided, offenders must be appropriately matched to the service based on their risk level.

Application

Not only is there research to support the harmful effects of exposing low-risk individuals to intensive correctional interventions, there is also much evidence to support that the strongest treatment effects are seen when moderate- to high-risk individuals are placed in intensive correctional interventions. Hence, while some speculate that the highest risk offenders may not be amenable to rehabilitation, research does not support this. Well-designed correctional programs that adhere to the RNR principles have been shown to significantly reduce the likelihood of recidivism for this higher risk group. They have the most to gain from treatment.

Thus, the crux of the risk principle is (a) assess risk using a validated risk assessment and (b) use

that information to match offenders to the appropriate level program. Beyond adopting a risk assessment and determining appropriate placement or admission into programs or services, other ways that programs implement the risk principle are by (a) separating offenders by risk level and (b) varying the dosage of an intervention by risk level. Although correctional programs may attempt to control program admissions, there are times when judges mandate offenders to intensive programs based on seriousness of the crime, irrespective of risk. Many facilities still have the ability to design their program so that the higher risk offenders are separated from the lower risk offenders. This might be accomplished by assigning offenders to pods, dorms, caseloads, or groups based on risk level.

In addition to separating by risk, programs can move away from a one-size-fits-all approach to treatment and supervision. Programs can explore ways to vary treatment dosage (or number of required treatment hours) by risk level, ensuring that higher risk offenders receive the highest dosage of treatment within a program. For supervision agencies, such as probation departments, jurisdictions may have low-risk caseloads where individuals are placed on probation for a shorter period of time and reporting requirements are less intensive (vs., e.g., every probationer being seen monthly for supervision). Such agencies also limit who can be placed on intensive caseloads to higher risk individuals to help ensure appropriate matching is taking place.

In conclusion, the risk principle is one of the three RNR principles of effective intervention. This principle suggests that intensive correctional programs target moderate- to high-risk individuals and that such individuals are identified via the use of validated risk assessment. Programs that adhere to the risk principle have stronger outcomes than programs that ignore this principle. Stronger outcomes for corrections-based programs equate to improved community safety.

RISK PRINCIPLE, ILLUSTRATIVE APPLICATIONS OF

Once an individual is involved in the criminal justice system, the chance of him or her getting into legal trouble again can be predicted with a fair degree of certainty. Some people are more likely to reoffend, whereas others are less likely. The *risk principle* states that criminal behavior can be predicted, and the risk level of the offender can be determined with some accuracy. In this way, offender risk to reoffend can vary. The risk principle also states that interventions should match

the offender's risk level so that higher risk individuals receive more treatment and services than lower risk offenders.

This entry examines the risk principle by providing a definition of risk and a description of the major risk factors for future criminal conduct. The three elements of the risk principle are introduced and described. Finally, the application of the risk principle is explored as it generally applies to offenders as well as specific offender populations (e.g., sex offenders and females).

Risk

Within the context of the offender population, *risk* is defined as the probability of continuing to commit a crime. Thus, the level of risk can vary where individuals can be more (high risk) or less (low risk) likely to reoffend. People who are at a higher risk to reoffend, for example, tend to commit another criminal act 60% of the time, whereas lower risk individuals only reoffend 10% of the time. This example also highlights that the risk to reoffend is only defined as the likelihood of reoffending, and sometimes, higher risk offenders do not reoffend and lower risk offenders do reoffend.

Importantly, this probability of reoffending is distinct from the seriousness of the crime. A person is not high risk simply because of the seriousness of their offense. For example, someone who has been charged with murder, a very serious offense, may actually be of low risk to commit another crime and may never do so. However, someone who has been charged with shoplifting a candy bar from the local convenient store may be identified as high risk and return to the criminal justice system again. Therefore, a person is high or low risk based on a set of characteristics that have been proven to influence the likelihood of reoffending, not because of the seriousness of the offense.

Risk Factors

It is important to define those characteristics that influence a person's risk to reoffend. Relying on a large body of research that identifies the most strongly correlated risk factors for reoffending, the major risk factors have been pinpointed. These risk factors include

- history of antisocial behavior,
- antisocial cognitions,
- antisocial peers,
- antisocial personality pattern,
- family/marital circumstances,
- school/work,
- leisure/recreation, and
- substance abuse.

The more risk factors present, the greater one's risk to reoffend. Higher risk individuals have many risk factors, whereas lower risk offenders have less risk factors.

The big four risk factors (history of antisocial behavior, antisocial cognitions, antisocial peers, and antisocial personality pattern), as coined by popular Canadian researchers, have the strongest influence on a person's risk to reoffend. The history of antisocial behavior includes not only the seriousness of the offense, but more importantly, the age at which the individual started engaging in criminal behavior, the number of times the person has been involved in the criminal justice system, and the type of criminal acts (e.g., property vs. violent offenses).

Antisocial cognitions include the attitudes, values, and beliefs one has that support criminal behavior. This can include statements that offenders might say to themselves to make it okay to steal someone's car (e.g., "I am sure they have insurance and will get an even better car") or to beat someone up (e.g., "He deserved it. He shouldn't have made me so mad").

Antisocial peers are those individuals with whom the person chooses to spend time with and who also engage in criminal behavior and support a criminal lifestyle. Related, this factor also considers isolation from prosocial individuals. A person who has no positive friends and only spends time with others who break the law is at greater risk to reoffend than someone who has both prosocial and antisocial friends. This is because peers model, reinforce, and punish behavior. If a person spends time with positive friends, then chances are that positive behavior is being modeled and reinforced. If a person is only spending time with antisocial peers, then only antisocial behavior is being modeled and reinforced, and chances are that prosocial behavior is being discouraged.

Finally, the risk factor, antisocial personality characteristics, concerns those traits within a person such as low self-control, poor problem-solving skills, impulsivity, hostility, and overly aggressive behavior.

Although not the risk factors of greatest influence, family/marital circumstances, school/work, leisure/recreation, and substance abuse factors do substantially influence the likelihood of reoffending. Family/marital circumstances can be risky when the quality of the interpersonal relationships within the family is poor, and the expectations for prosocial behavior are weak. For example, when the relationships lack care, concern, and respect, and instead are filled with conflict and contempt, the risk factor is present. Similarly, when the experience at school and/or work includes minimal involvement and poor relationships, if any, rather than filled with positive high-quality relationships, there is risk. The key with these two factors lies in whether or not the individual is connected to prosocial others in their life and whether or not the person sees those relationships as rewarding and positive. Related, how people choose to spend their free time can influence their risk to reoffend. Individuals who are involved in rewarding prosocial activities are more likely to avoid trouble with the law than individuals who lack involvement in similar activities. Finally, substance abuse is often illegal in and of itself. Moreover, the act of purchasing illicit drugs involves contact with antisocial others, while using substances often decreases one's self-control.

Within the major risk factors described above, both static and dynamic factors have been distinguished. *Static risk factors* are those risk factors that cannot change. For example, criminal history is a static risk factor because one cannot go back and change a criminal event that happened in the past. On the other hand, *dynamic risk factors* are those risk factors that are changeable. Self-control and problem-solving skills can improve. Likewise, individuals can learn ways to manage their anger and change the way they think. For example, "She shouldn't have cut me off like that, so I'm going to show her" is an example of risky thinking that could lead someone to reckless and dangerous driving. To change those thoughts, someone might then think, "But I don't want to get hurt or hurt someone else. Clearly she is in a hurry, so I am just

going to let her go on.” New thinking can lead to new behavior. Knowing the static and dynamic risk factors means that the risk to reoffend can be determined. If someone has many of these risk factors, they are at higher risk to reoffend than someone who only has one or two risk factors.

The Risk Principle

Since the early 1980s, psychologists from Canada have been researching what works to change offender behavior. In 1990, they presented the risk principle, among others, as a means to guide effective correctional treatment. The risk principle states that criminal behavior can be predicted and that the level of treatment should be matched to the risk level of the offender. This means that higher risk individuals should receive treatment that is of greater intensity and length than individuals who are identified as low risk.

In this way, there are three main elements to the risk principle. The first states that correctional programs should target those offenders with higher probabilities of reoffending. This means that the risk to reoffend needs to be determined so that services can be prioritized to those who have the greatest risk. A common way corrections professionals identify risk is through the use of a risk assessment instrument. A *risk assessment instrument* is a tool that examines the major risk factors for reoffending (e.g., history of antisocial behavior, antisocial cognitions, antisocial peers, antisocial personality pattern) and places offenders into categories (e.g., low, moderate, and high) that allow agencies to separate offenders by risk. Once the risk level is determined, treatment and supervision services are then provided so that higher risk offenders receive more treatment than lower risk offenders, which leads to the second element.

Highlighting the importance of matching, the second element of the risk principle states that most intensive treatment should be provided to higher risk offenders. For example, a higher risk person might receive anger management services and substance abuse treatment and participate in a program designed to address antisocial thinking. A low-risk person might only receive substance abuse treatment. Generally speaking, research to date suggests that higher risk offenders require at least 200 hours of treatment in order to reduce

their risk to reoffend. This treatment should target multiple risk factors (e.g., antisocial cognitions, peers and personality characteristics) and use strategies that have been shown to work at changing offender behavior.

Finally, the third element of the risk principle notes that intensive treatment for lower risk offenders can increase recidivism. For example, a large study of over 20,000 offenders found that when lower risk offenders were provided a similar level and length of treatment as higher risk offenders, the lower risk offenders' failure rates increased. This element suggests that lower risk offenders should only receive services in areas in which they have a need in the least restrictive setting. For example, a low-risk offender who does not have a substance abuse problem should not receive substance abuse treatment. However, a low-risk offender who finds it difficult to manage anger should receive anger management services.

Importantly, this element emphasizes that any service a low-risk offender receives should be separated from higher risk offenders. Mixing low-risk offenders with higher risk offenders often means that the lower risk individuals will learn antisocial attitudes, values, beliefs, and behaviors from the high-risk offenders. Moreover, the very things that make a person low risk (e.g., quality relationships with family, prosocial friends, job stability) are disrupted when high levels of treatment and supervision are provided. For example, strain is placed on relationships at home, causing discord and contempt; individuals often lose their job because they have to participate in treatment services and miss too much work; and prosocial friends may no longer want to spend time with someone who has been to prison.

Research

Research has been conducted on the risk principle since the 1990s and has demonstrated that when services are delivered to higher risk offenders (rather than lower risk offenders), the risk to reoffend for those higher risk offenders is reduced. Furthermore, some studies have shown that when lower risk offenders receive more treatment than they should, their risk to reoffend increases. Certainly, this is not what the field of corrections aims

to achieve. These findings have been replicated with both male and female offenders as well as juvenile and adult offenders. More recently, research from Canada and Ohio has shown that the risk principle also applies to sex offenders. In this way, the risk principle does not discriminate by offender type and is considered one of the core principles of effective correctional intervention. Programs that fail to adhere to the risk principle can expect to have little to no impact on recidivism and in some cases actually increase recidivism.

RISK-NEED-RESPONSIVITY, APPLICATION TO FEMALE OFFENDERS

In response to the growing number of females under correctional supervision, researchers and policy developers have shown a marked interest in exploring the situations and circumstances that place this demographic at risk of criminal justice involvement. Gender-neutral theorists holding to the Risk-Need-Responsivity (RNR) perspective argue that with respect to the etiological components of their criminal conduct, similar theories, risk factors, and general treatment strategies generalize to both male and female offenders. In contrast, feminist scholars contend that justice-involved women follow unique pathways into crime and that correctional protocols that were developed largely on the basis of male samples fail to capture the unique circumstances of women. This entry articulates both gender-neutral (RNR) and gender-responsive perspectives on criminal conduct and presents evidence for an integrative theoretical approach.

Principles of RNR: A Gender-Neutral Approach

Grounded in the *personal, interpersonal, community-reinforcement* theory of criminal conduct first articulated by Canadian researchers Don Andrews and James Bonta, the principles of risk, need, and responsivity (commonly referred to as RNR or *What Works*) constitute the operational derivative of this mainstream gender-neutral framework.

The *risk principle* states that correctional treatment intensity—as defined by the frequency of program sessions, program length, or some combination of the two—should be tailored to one's risk to reoffend, with the most intensive

interventions reserved for the highest risk offenders. Research has consistently demonstrated that providing intense correctional interventions to low-risk individuals will, at best, have a nil effect and, at worse, result in increased recidivism.

In turn, the *need principle* states that effective correctional treatment should target dynamic risk factors (also termed *criminogenic needs*) that are both malleable and predictive of criminal conduct. According to the RNR literature, the individual-level factors most predictive of recidivism (i.e., the Big Four) include (a) attitudes supportive of crime, (b) antisocial peers, (c) criminal history, and (d) antisocial personality factors (e.g., poor impulse control). These are followed by (e) substance abuse, (f) disruptions within the family, (g) deficits in employment and education, and (h) inappropriate use of leisure time. These domains are collectively termed the *Central Eight*, which according to proponents of the RNR perspective, account for individual differences in criminal conduct irrespective of gender, race, or social class. Relative to the Central Eight, research has demonstrated that level of intelligence, socioeconomic status, and measures of personal distress are weak predictors of crime.

The last core principle of effective correctional treatment is the *responsivity principle*, which is related to the manner in which a program is delivered. The *general responsivity principle* posits that the most effective correctional programs incorporate cognitive behavioral and social learning principles including modeling, shaping, behavioral rehearsal, and cognitive restructuring. In turn, the *specific responsivity principle* holds that intervention strategies should be sensitive to the characteristics of the offender, considering such factors as level of intelligence, social anxiety, mental health issues, and minority status. Under the RNR framework, gender is considered a specific responsivity factor; in other words, although some minor adjustments might be made to treatment programs delivered to women, the Central Eight predictors of criminal behavior and general treatment strategies endorsed by RNR proponents are said to hold regardless of gender.

Since the 1990s, a vast body of empirical literature has accumulated to support the validity of the RNR model for both male and female offenders. Specifically, compared to untreated groups,

adherence to the three principles of effective correctional intervention has produced up to a 40% reduction in recidivism rates. Moreover, multiple investigations have shown that at the aggregate level (i.e., when analyses are based on an overall risk score), gender-neutral risk assessment protocols that incorporate the Central Eight generally attain similar levels of accuracy when applied to both male and female samples.

Criticisms of RNR

Despite promising results generated by the application of the RNR model across gender, a number of feminist scholars have levied theoretical and methodological criticisms against the gender-neutral approach to correctional processing for women. Namely, the early empirical evidence in support of the RNR framework rested predominantly on male samples and/or relied on studies that failed to disaggregate samples by gender. Including a proportion of males (typically the majority subgroup) in a sample intended to be generalized to females can potentially mask important risk factors that may, in fact, be important for women. Furthermore, gender-neutral proponents operate on the premise that the same set of factors that predict criminal conduct for males will extend to females, engendering the possibility of neglecting key etiological nuances that are either female-specific or experienced qualitatively differently by women.

One issue of particular concern with respect to the use of gender-neutral tools with girls and women is that of *overclassification*—the result of placing an individual in a higher risk category than is actually warranted based on the level of threat posed by that person's behavior. Given that, on average, women score lower than men on risk assessment tools and have lower base rates of offending, a woman's score must be higher than a man's before a given custody level will show comparable levels of recidivism. Most gender-neutral proponents recognize this issue, and in the majority of criminal justice agencies across North America, risk classification schemes are adjusted to reflect the lower probability of reoffending among justice-involved women—even when an otherwise *gender-neutral* assessment tool is adopted.

However, even with instrument recalibration, misclassification can still occur if the assessment protocol is not valid at the outset. A number of feminist criminologists posit that while RNR principles may apply to women in a general sense, justice-involved women have unique criminogenic needs that are not adequately represented within mainstream correctional protocols.

Relational-Cultural Theory (RCT) and Feminist Pathways

RCT and the *feminist pathways* perspective are the literatures most often cited to underscore gender differences in the etiology of criminal conduct. Based primarily on qualitative data gathered through extensive interviews with justice-involved girls and women, relational-cultural theorists argue that while many justice-involved males are subject to childhood abuse or neglect, the experience of relationally based trauma among girls is qualitatively different. In contrast to traditional psychodynamic theories extolling individuation and autonomy as healthy developmental milestones, *RCT* views connectedness as the basic human motive and hallmark of mature functioning. Although the desire to form empathic connections is said to be innate for males and females alike, differential socialization creates a disparity across genders in both the motivation and capacity for connectedness. Specifically, while males are taught to value individual achievement-oriented goals, females are taught to place ultimate worth on forging meaningful relationships. As such, *RCT* theorists contend that early *relational disruptions* through abuse and neglect—often persisting into adulthood in the context of unhealthy romantic attachments—are particularly detrimental to young girls and serve to catalyze their trajectory into crime.

Similarly, feminist pathways proponents emphasize the impact of maladaptive family relationships in the genesis of female-perpetrated crime. While family process variables are established risk indicators for male delinquency and encompassed in the Central Eight, relationship-based factors are argued to be particularly salient to female offending. Although there are exceptions to the rule, according to both qualitative and quantitative research, a common female *pathway*

into crime entails some variation of the following: Victimized sexually and/or physically in her home of origin (typically by a male), the abused young woman eventually flees only to find herself living on the streets. Likely dealing with mental health and substance abuse issues ensuing from her early trauma, the young woman is unable to support herself due to a curtailed education and lack of vocational skills. Ultimately, she becomes enmeshed in a life of petty crime related to survival needs. Women adhering to this pathway are often desperate to maintain relationships and gain the acceptance of male intimates encountered within the criminal subculture. Accordingly, these women may be particularly inclined to pursue lawbreaking activities as a product of their association with criminal male partners who may further exploit them as sexual capital.

Gender-Responsive Needs

Despite childhood maltreatment and adversarial interpersonal relationships being pervasive in the histories of both male and female offenders, empirical studies suggest that these indicators exert a greater criminogenic impact on girls. Consistent with the tenets of *RCT*, relational disruptions—even in lesser orders of magnitude such as the inadequate demonstration of love by caregivers—are particularly important risk factors for criminal outcomes among girls.

Collectively, justice-involved females do in fact profile with higher rates of direct victimization than their male counterparts (particularly in the form of sexual abuse), endure more pervasive family conflict, and experience more ensuing psychiatric issues. As per the feminist pathways perspective, a history of trauma is a significant precursor to mental health disturbances, including post-traumatic stress disorder, depression, anxiety, and self-injurious behavior. In a 2016 investigation, Sarah Walker and colleagues make the argument that given equally maladaptive, conflict-ridden homes, a female's greater exposure to the home environment, coupled with the relational orientation of girls, provides insight into the more pronounced negative impact of early childhood adversity on girls relative to boys.

Given that mental health is considered non-criminogenic under the gender-neutral RNR

model, this factor is featured far less prominently than the Central Eight in associated risk assessment tools. Indeed, most research indicates that aggregate measures of personal and emotional distress tend not to bear a significant relationship to criminal recidivism, even among justice-involved females. However, unpacking the construct of mental health into specific diagnoses has revealed that current mental health needs including depression, anxiety, and post-traumatic stress disorder can be predictive of criminal recidivism among female offenders.

Although substance misuse has been underscored as an important criminogenic need for both males and females as per the gender-neutral literature, there is evidence to suggest that justice-involved females have higher rates of substance dependence compared to justice-involved males and may rely on substances for different reasons. Both U.S. and Canadian statistics support the high co-occurrence of diagnosed mental health conditions and substance abuse among incarcerated women. Qualitative studies have suggested that while males are more likely to abuse drugs and alcohol as a result of peer pressure or to experience hedonistic effects, the genesis of substance abuse among women lies in an attempt to mask the emotional impact of an extensive history of trauma, victimization, and ensuing mental health disturbances.

Gender-Responsive Risk Assessment

Correctional researchers informed by both RNR and feminist perspectives have contributed sound empirical evidence to support the merit of considering gender-responsive factors in tandem with gender-neutral factors in the prediction of criminal conduct. Multiple investigations have shown that a collection of factors tied to childhood and adult victimization, low self-efficacy, mental health issues (e.g., active diagnoses of depression, anxiety, psychosis, and/or self-harm), poverty, and parental stress culminate in a criminal lifestyle among women.

In a seminal investigation published in 2010, Patricia Van Voorhis and colleagues examined whether a series of gender-responsive scales would enhance the ability of gender-neutral scales to predict recidivism outcomes. Drawing from prison,

probation, and prerelease samples of women across four U.S. states, they determined that the overall gender-responsive supplement did offer incremental predictive validity over and above the gender-neutral model. In a study from 2014, Krista Gehring and Patricia Van Voorhis yielded comparable findings in a sample of pretrial defendants, this time including a male comparison group. For the male sample, none of the gender-responsive scales (including abuse, trauma, mental health, homelessness, and family support) were predictive of new arrests. Among women, however, when the gender-responsive scales were considered along with the gender-neutral scales, the relationship between assessment scores and negative outcomes was significantly enhanced.

There is a growing body of research to suggest that a consideration of gender in correctional settings may be more than a responsivity issue. Indeed, there is evidence to suggest that employing gender-responsive risk assessment strategies has the potential to optimize the correctional processing of female offenders insofar as (a) improving the accuracy of risk assessment tools in predicting future crime committed by women and (b) appropriately informing treatment options for justice-involved women.

Gender-Responsive Programming

Grounded in the principles of social learning, RNR-based correctional programs termed *gender-neutral* have traditionally been applied to both male and female offenders—with very few if any modifications. By contrast, programs designed to be gender-responsive can explicitly account for women's unique pathways into crime by addressing both common and unique social, cultural, and psychological factors that led to their criminal involvement. Beyond an adherence to the core RNR framework, gender-responsive models are relational, trauma-informed, and strengths-based. Specifically, programming strategies encourage women to identify and cultivate existing talents and abilities, and foster collaborative approaches to case planning that grant women the decision-making power with respect to intervention goals. Recognizing the pervasive and complex mental health needs of female offenders, multidimensional treatment services are offered

that target mental health disorders and substance abuse concurrently within a trauma-informed framework.

In a 2016 study, Renee Gobeil and colleagues examined the differential effectiveness of gender-neutral versus gender-responsive interventions in reducing recidivism among justice-involved women. Systematically pooling the results of 37 studies that collectively included 22,000 women, both intervention options initially appeared to be equally effective, with treated groups demonstrating up to 35% greater odds of success compared with untreated groups. However, when restricting their analyses to studies of higher methodological quality, the gender-responsive interventions produced significantly greater recidivism reduction effects than gender-neutral options. This critical investigation supports a growing body of literature demonstrating that correctional processing of female offenders can be improved when RNR principles are augmented by an explicit consideration of gender-responsive options.

RISK-NEED-RESPONSIVITY, PRINCIPLES OF

The Risk-Need-Responsivity (RNR) model is a favored framework in contemporary criminal justice settings. It has three core principles: (1) identify the static risk level of the individual, (2) identify the dynamic risk factors (needs) that are associated with offending behavior, and (3) identify appropriate correctional interventions that are suitable to address the risk–need interaction. The RNR framework applies to decisions at the individual level regarding how best to address the factors that contribute to engagement in criminal behavior. But, it also applies to the system level in terms of the capacity of agencies or jurisdictions to have available and use an array of services tailored to the needs of individuals involved in the justice system. Responsive systems use RNR principles as part of an overall scheme to reduce recidivism through evidence-based programming, practice, and treatments.

Model Components

The core components of the RNR model are as follows:

- **Risk**—Risk level is used to address the degree of social control. It focuses correctional supervision and/or treatment efforts on those assessed by validated tools as at risk of reoffending. Lower risk offenders are minimally supervised, and higher risk individuals are more intensively supervised and treated.
- **Need**—This component targets criminogenic needs that are directly related to recidivism. In 2010, Don Andrews and James Bonta identified the following criminogenic needs to be directly related to recidivism: antisocial values, antisocial peers, antisocial personality, and antisocial history. Secondary, less directly related

criminogenic needs are substance dependence, education, employment, and leisure.

- *Responsivity*—This component comprises two types: general responsivity and specific responsivity. With *general responsivity*, evidence-based behavioral, social learning, and cognitive behavioral treatment strategies are employed to address risk–need profiles of individuals. *Specific responsivity* refers to adapting the style and model of service according to the setting of the service and to relevant characteristics of individual offenders, such as their motivations, literacy, developmental stage, age, gender, ethnicity, cultural identifications, among other factors.

To more effectively use the RNR framework, criminal justice agencies should have (a) a validated risk assessment instrument identifying static risk and prioritizing higher risk individuals for more intensive services and controls; (b) a validated needs assessment tool or cadre of instruments to identify dynamic risk, or offender needs, related to recidivism (e.g., antisocial cognitions, antisocial peers, substance abuse) that is prioritized for intervention based on the availability of appropriate and effective treatment programs; and (c) appropriate supervision and treatment staff who respond to offender risk and need by utilizing evidence-based practices and treatments grounded in behavioral and cognitive behavioral models. Programming and treatments should be sensitive to the risk–need profile of individuals, particularly issues to correctional services that affect receptivity such as gender responsiveness, literacy, mental health issues, treatment readiness, cultural responsiveness, and other major issues.

Risk

Risk refers to the likelihood of having further interaction with the justice system. Risk generally relates to the person's prior involvement with the justice system such as the number of prior arrests, number of prior convictions, number of prior incarcerations, number of times revoked probation, and other justice involvement. Sometimes involvement with drugs at the time of arrest is also included. Risk is considered static in that it refers to past actions—whereby the past refers to the

future. In this sense, risk alone cannot decrease since an individual cannot erase his or her past.

Needs

The RNR model focuses attention on seven offender needs: antisocial personality pattern, antisocial cognitions or thinking, antisocial associates, family or marital problems, low levels of education or financial achievement, lack of prosocial leisure activities, and substance abuse as directly related to recidivism. Along with these factors are a set of factors indirectly related to recidivism that affects responsiveness to programming such as mental illness, literacy, mental challenges, and motivation. These factors are considered stabilizers when they serve as protective factors, or they can be destabilizers when they detract from functionality of an individual. The need principle of the RNR framework relies upon standard and validated screening and assessment instruments to identify dynamic offender needs to prioritize targets for interventions but can neglect the influence of factors that stabilize an individual but may not be considered criminogenic.

The following subsections discuss some of the most common needs among offender populations as well as stabilizing factors that share some characteristics of dynamic needs but expand the perspective on including them in assessment tools.

Substance Use

Some substance use behaviors (i.e., use of opioids, crack, methamphetamines) drive criminal behavior, whereas other substance use behaviors may be more entrenched in a lifestyle for recreational purposes (e.g., alcohol). This distinction is best made when a validated instrument is used to provide information about lifetime use of drugs, drug of choice, mode of delivery (e.g., smoking, injection), longest periods of abstinence, current usage, and whether drug use affects employment or is related to legal problems. While the drug use and crime relationship is complicated, an important consideration is whether criminal behavior is due to the psychopharmacological use or involvement in offending behavior to obtain funds for drugs. That is, the individual is under correctional control for possessing/using drugs or committing

other types of crimes to get money for drugs. Based on this information, different substance abuse treatment programs are needed to better serve the individual. It is especially important to prioritize treatment needs based on substance use disorder severity and drug of choice. Research has shown a link between dependency on hard drugs (e.g., cocaine, opiates, amphetamines) and offending, which makes hard drug dependence, and crimes associated with this type of use, a criminogenic need, and thus should be prioritized for treatment in the justice system.

Antisocial Cognitions and Thinking

Antisocial cognitions, or thinking errors, are the means by which people rationalize their deviant behavior to neutralize or reduce the negative consequences resulting from offending. Typical thinking errors include dominance, entitlement, self-justification, displacing blame, optimistic perceptions of realities, and *victim stance* (e.g., blaming society because they are considered outcasts). These exaggerated or distorted thinking patterns are a primary target of the behavioral and cognitive behavioral treatment approaches recommended under the general responsivity principle of the RNR framework. As a criminogenic need, criminal thinking and antisocial cognitions should be prioritized for treatment during correctional supervision and with greater specificity by considering other present dynamic needs. For instance, there may be differences in thinking errors related to marijuana use versus harder drug use that might be best addressed by programs attending to these errors, as opposed to a *one-size-fits-all* approach.

Antisocial Personality Pattern

According to diagnostic criteria in the American Psychiatric Association's *Diagnostic and Statistical Manual for Mental Disorders, Fifth Edition*, antisocial personality disorder is characterized by a callous disregard for the feelings of others; gross or persistent attitude of irresponsibility; disregard for social norms, rules, or obligations; incapacity to maintain enduring relationships; low tolerance, frustration, and use of aggression or violence; incapacity to experience guilt or to profit from

experience; or marked proneness to blame others for the behavior that the person exhibits. Many criminologists and psychologists consider measures of antisocial personality disorder to be as close to a diagnostic criterion for criminal personality as exists.

Antisocial Associates and Social Supports

The RNR framework emphasizes antisocial associates (family and peers) as a criminogenic need, while recognizing prosocial family and peers as a protective factor against continued involvement in offending. Family and friends (referred to as *social ties*) can provide emotional support and facilitate the offender change process. Three mechanisms through which social ties may foster desistance are (1) informal social control by promoting normative behavior, (2) emotional support that improves low self-esteem and negative emotionality, and (3) facilitation of a transformation in identity from offender to citizen rather than reinforcement of an offender identity. Accordingly, the RNR framework stresses identifying family and friends as either supportive of or detrimental to a crime-free lifestyle and prioritizing antisocial associates as a criminogenic need to address to improve the likelihood of desistance from crime and/or drug use.

Employment and Educational Attainment

Offenders tend to have lower educational attainment than the general population, and prior research has found that individuals who do not graduate from high school are more likely to recidivate than those who do graduate from high school. But, failing to complete high school is not criminogenic in that it does not *cause* a person to commit crimes; instead, it may affect verbal intelligence or literacy levels. Much of the impact of education on recidivism outcomes may operate through its impact on employment, which has generally received more empirical support as a correlate of recidivism outcomes. Because it is not directly related to recidivism, education is considered a noncriminogenic dynamic need that requires less treatment attention than criminogenic needs; however, employment interventions that target behavioral modification demonstrate success.

Responsivity

The concept of responsivity has evolved into more of a general principle for matching the appropriate type of programming based on the risk and need factors of individuals than attending to individual characteristics. Embedded in this conceptualization of responsivity is a number of program- or intervention-level factors that affect the quality and potential impact of the programming that should also be considered when determining the most appropriate level of correctional intervention for a justice-involved individual. These additional program features include the dosage, program content, the fidelity or adherence to the program model, and the quality of the program resources.

- *Dosage*, or the number of hours that a person is involved in the correctional program, should vary by risk level, and higher risk offenders should be involved in larger quantities of programming.
- *Content*, or the theoretical orientation of the intervention, should include cognitive behavioral therapy, therapeutic communities, or integrated service models like drug treatment courts. The foundational nature of the treatment programming has an impact on results.
- *Fidelity*, adherence to core correctional practices, or the degree to which the program is implemented as planned, is directly related to program effectiveness. This construct reflects the dosage, content and curriculum, type of staff, and other key components of the program that are essential for retaining their evidence base but often overlooked in the responsivity principle.
- *Program resources*, which includes facilities, resources, and staffing available to the program, should be aligned with the intended goals of the intervention. Program resources are important to ensure that the clinical or responsivity components are adequately resourced to demonstrate fidelity and be effective.

Based on a review of the literature and current knowledge about program effectiveness, decision criteria for responsivity include the following:

1. The combination of risk–need profiles defines various problems, ranging in severity, which

should be integrated into the RNR framework. The responsivity principle should consider all dynamic offender needs, including the host of clinically relevant, noncriminogenic factors in identifying problem severity. Considering this, complexity in matching services can result in better effectiveness and efficiency in changing behavior.

2. Substance use dependency and criminal lifestyle should be prioritized for more structured, intensive programming. These severe behavioral issues generally require more intensive services, particularly for moderate- to high-risk offenders.
3. Age, developmental stage, and gender are important responsivity factors that should adjust the content of the program/services to better address needs impacted by these demographic categories.
4. Programming content should be categorized into four types: cognitive and behavioral, interpersonal and social skills, lifestyle skills, and punishment (no programming). Cognitive and behavioral programming should be the primary intervention type for individuals who are moderate to high risk with criminogenic needs, since these models have been reported to have the greatest empirical base linked to reduced recidivism.

Impact of the RNR Model

The original RNR framework has had a positive impact on the growth of evidence-based programming and treatments in the field of corrections. The model has identified the importance of individual-level factors in making determinations about the appropriate level of programming that is needed. However, further refinement of the various criminogenic needs in the RNR framework is warranted. For example, more research is needed to examine how these individual factors affect participation in different types of programming or the type of programming that is likely to reduce recidivism for specific profiles of offenders.

Adhering to the principles of the RNR framework at a system level can lead to reduced

recidivism rates and improved cost-effectiveness of the U.S. correctional system. The RNR model combines several evidence-based correctional practices into a single, versatile framework. A particularly valuable component of the RNR framework is its potential to guide resource allocation and improve the fit between correctional interventions and individual offender needs. The framework stresses the importance of building a human services culture within the correctional system: a goal that empirical evidence has shown is more effective at reducing recidivism than incarceration or sanctioning alone. In a time when correctional resources are sparse, the RNR framework offers a model to efficiently and cost-effectively respond to the needs of the offender population. The framework offers not only improved cost-effectiveness but also improved public safety returns.

ROBBERY

Both street robbery and commercial robbery fit the general definition of robbery as involving theft or attempted theft by force or the threat of violence. It should be noted, however, that there are significant differences between the two. They involve for the most part a different set of perpetrators, exercising different forms of force, directed at a different set of victims and targets. In jurisdictions in which both forms of robbery are conflated, it may be the case that street robbery is increasing while commercial robbery is decreasing, and the net result in the official figures is that the incidence of robbery remains level. Another significant feature of robbery is that it is an offense that combines both property crime with that of interpersonal violence. This entry discusses robbery and its relation to violence, victim selection, the amounts of money and goods stolen, and the role of the police as well as the changing nature of robbery.

On Violence

Although violence is socially and historically seen as widespread, there is little understanding of the emotional dynamics of violence. Randall Collins argues that rather than being natural or easy to carry out, violent situations are characterized by tension and fear. He suggests that persons in violence-threatening situations experience tension and fear. This consequently results in most forms of interpersonal violence being aborted, or alternatively, it is clumsy, imprecise, and uncontrolled. Overcoming these fears requires developing certain forms of self-control.

Thus, Collins argues that the issue for those who plan to use violence is how to prolong violent encounters for more than a few seconds. For the robber, this is the main challenge. To prolong violence requires learning to control one's body rhythms or creating a situation of immediate and total dominance by a display of force or by selecting a weak victim.

Typically, muggers seek out victims who are smaller and/or physically weaker and often with the advantage of two or three against one. Robbers who carry a weapon have an immediate advantage over unarmed victims, but they still tend to choose a moment when their victim is off guard and can be physically and emotionally dominated. The aim among armed robbers is to gain total control not just physically but also emotionally.

A standard strategy of professional armed robbers is to create mayhem and to demonstrate such a show of force that victims and onlookers quickly become compliant. Thus, a widely used *modus operandi* adopted by those engaging in commercial robberies is to smash the counter screens with a hammer or fire shots into the ceiling. In both cases, the aim is to create a large amount of mess and disruption in order to eradicate any potential resistance.

Injuring or killing a victim is detrimental to the objective of getting the money or goods and escaping as quickly as possible. Injuring victims can be a major impediment to conducting the robbery and may lead to committing a more serious crime carrying longer jail time. Indeed, there is an inverse relationship between the display of force and the likelihood of an injury. Paradoxically, the more force used, the less likely it is that there will be resistance and an injury. However, when

ineffective and unconvincing weapons are used (e.g., a small knife), there is a greater chance of victim retaliation. All of these factors make violence unpredictable. Therefore, there is always the propensity for a robbery to turn into something more serious or even disastrous.

Victim Selection

Besides targeting weak individuals and trying to gain emotional and physical control, robbers tend to select victims in much the same way as other offenders. As Richard Sparks pointed out in a 1981 article, the selection of victims is not random, and there are some people who can be described as victim-prone.

Although there is some degree of rationality in victim selection, mainly in terms of accessibility, attractiveness, and vulnerability, it is something of an exaggeration to see the selection of the victim or target as the outcome of a strictly rational process. For the robber, targeting a commercial premises or an individual victim may be highly structured and circumscribed. However, robbers are also influenced by a number of contingencies and are guided by hunches, prejudices, and intuitions as well as other irrational considerations. As Dermott Walsh points out in his 1986 discussion of victim selection, robbers will often refrain from a robbery because it does not *feel right*. Walsh also points to the role of luck and fatalism in influencing decisions. Within this complex framework, the apparent rationality of the decision-making process attributed to the offender may actually be a rationale imposed by the researcher after the event rather than an accurate depiction of the actual decision-making process itself.

Robbers will often choose sites with which they are familiar. Such sites are more likely to *feel right*. Being familiar with a particular premises or area can have a significant influence on the offender's sense of control and in some cases his or her ability to find an escape route. This in part explains why there is such a high level of repeats in relation to commercial robbery. Research by Peter van Koppen and Robert Jansen in the Netherlands has indicated that more professional robbers will normally be prepared to travel further afield in search of more lucrative targets, whereas more inexperienced robbers will tend to choose targets close to home.

The Meaning of Money

In many cases of robbery, the offenders have only a vague idea of the amount of money they might get. Occasionally, they are pleasantly surprised, as with the famous Brinks Matt robbery in 1983 at Heathrow airport involving a record £26 million worth of gold bullion, diamonds, and cash. Most of the time, however, they are disappointed.

When targets are selected with little or no planning, the amount of money available is largely a matter of luck. However, even among the more experienced commercial robbers, there is a considerable amount of guesswork because different commercial organizations have learned to remove cash from the premises on a regular basis to vary the amounts held at any one time. A review of robberies carried out in London between 1994 and 1995 found that there were considerable differences in the average take from different types of commercial premises. The premises that had the highest level of takings were found to be jewelers followed by cash in transit. According to a 1996 report by Shona Morrison and Ian O'Donnell, the takings from banks were in the region of £3,000 and £4,000. In the United States, it is estimated that the average takings from a bank robbery is around US\$4,000.

Research based on convicted armed robbers in prison found that one in three commercial robberies are unsuccessful and nothing is taken. In a number of cases, the amount stolen was less than £500. In many cases, robberies are poorly planned, and the offenders are caught and therefore unable to spend the money that they have stolen.

Policing Robbery

The strategies that have been used to deal with both street robbery and commercial robbery have been fairly diverse. Different forms of target hardening as well as strategies have been implemented to increase risk and reduce rewards. Marking goods and installing security devices, for example in the case of mobile phones, have been widely adopted. It is also recognized that street robbery tends to be located in specific areas, and measures can be taken to monitor these sites by installing surveillance systems or making them less attractive through forms of environmental design.

In relation to commercial robbery, an array of security measures including screens, alarms, cameras, and of ink dye in security cases have been adopted since the 1980s. These are now standard features of many commercial premises.

For avid viewers of crime thrillers, there is a tendency to believe that most commercial robbers are caught through forms of surveillance or matching DNA samples or fingerprints. However, a detailed investigation into the policing of commercial robbery reveals that it is not through the gathering of forensic evidence or the use of closed-circuit television that robbers are caught. Rather, it is through the use of informants that most commercial robbers are apprehended. A study of 340 commercial robbers carried out in England and Wales in the 1990s found that the primary way offenders were apprehended was through the information and tips provided by informers. This study concluded that the principal method of detection in 40% of cases was information gathered from informants. The second most common strategy was through protracted police investigation. Surveillance, forensics, and video footage played a minor role as the principal reason for arrest and tended to serve as sources of confirmation during the process of prosecution. It was also found that there is some variation in the clear-up rates for different premises, with banks and building societies having a considerably higher clear-up rate than post offices, garages, or shops. This appears to be because those who rob post offices and shops tend to be inexperienced and in many cases unknown to the authorities, whereas those who target more lucrative targets are more professional criminals who are more easily identified by the authorities.

The Decrease in Robbery

In line with other offenses, the incidence of robbery has decreased in a number of different countries since the early 1990s. According to the Crime Survey for England and Wales, the number of robberies reported has fallen from 315 in 2007 to 252 in 2011. U.S. data from the Uniform Crime Reports indicate that the incidence of robbery has decreased from 146 per 100,000 in 2002 to 112 per 100,000 in 2012. Australia experienced a similar decline and decreased from 11,000 in 2001 incidents to 6,000 in 2005.

One of the leading explanations for the decrease in robbery and other offenses is the growing use of security measures as a result of which a wide range of targets are now better protected than they were in the past. Consequently, the risks associated with these crimes have increased, thereby deterring prospective offenders. Other explanations include the incapacitation effect of imprisonment, changing patterns of drug use, the development of new styles of policing, and demographic shifts.

Given the hundreds of million pounds and dollars spent since the 1980s, it is inconceivable that crime prevention and target hardening measures have not served to reduce armed robberies. However, in England and Wales, many of these measures were introduced in the 1980s, whereas the period for the most systematic decrease in armed robberies was from 1993 onward.

Probably more effective in reducing commercial robberies are those measures that are designed to prevent robbers from taking control. Strategies that increase uncertainty and introduce contingencies into the situation are likely to be most effective. These uncertainties can be maximized by changing the internal design of the premises, limiting the robbers range of vision, and by the staff employing delaying tactics.

Although such measures can be surprisingly effective, they are at best only partially responsible for the decrease in recorded robberies. What seems to be happening is a significant change in the cultural attributes of armed robbers. During the 1970s and 1980s, there were a relatively large number of career armed robbers in the United Kingdom who were organized and professional. Robberies were planned, firearms were carried, and escape routes identified. However, since the early 1990s, these career and professional robbers have been in decline. Dick Hobbes has argued that there has been a decline in the number of professional armed robbers and an increase in amateurs with a low level of competence operating with a minimal level of planning.

The image of the classic armed robber wearing a balaclava and overcoat and carrying a sawn-off shotgun appears to be a thing of the past. This change in turn seems to be linked to changing attitudes toward (male) violence as we move into a post-Fordist service economy that places less

value on strength, aggression, and the pursuit of interpersonal violence. As a result, the incidence and nature of robbery is changing involving a shift toward more amateurish, spontaneous attacks against weaker and less protected targets.

RUIZ V. ESTELLE (1980)

Ruiz v. Estelle is a significant case in U.S. jurisprudence regarding prison reform: It shaped modern-day practice and policy with regard to corrections management, prison reform, and judicial oversight. It was also the first of its kind: Prior to *Ruiz*, federal courts had avoided involvement in states' management of their prisons and prisoners. *Ruiz* continued through appeals and judicial oversight of reform efforts for decades, also spurring congressional lawmaking.

In 1972, inmate David Resendez Ruiz filed a petition against the Texas Department of Corrections (TDC) director William J. Estelle, alleging his incarceration conditions violated his rights under the U.S. Constitution. Ruiz's claim alleged violations of his Eighth Amendment right against cruel and unusual punishment and his Fourteenth Amendment right to due process of law, a right to receive fair procedures before being deprived of liberty. To support his claim, Ruiz described overcrowding, with two or three inmates being housed in cells designed for one; poor medical and mental health care in terms of quality, limited availability, and provision by other inmates and unlicensed/untrained civilian medical assistants; improper oversight, with guards assigning *building tenders* (specially chosen inmates) the duties of a corrections officer (including disciplinary authority); unsafe conditions, with inmates exposed to increased risk of harm given inadequate security; and general mistreatment, with inmates subjected to severe and sometimes arbitrary physical punishment by guards and building tenders.

Although an inmate of the state of Texas (and therefore subject to state jurisdiction over prison affairs), Ruiz, like all inmates, was entitled to federal court review of alleged breach of his Eighth and Fourteenth Amendment rights. In 1974, the petition became a class action suit when seven other inmates' petitions were consolidated with Ruiz's. In December 1980, Federal Chief Judge William Justice of the U.S. District Court for the Southern District of Texas agreed that the conditions of their imprisonment under the TDC was indeed a violation of their Eighth and Fourteenth Amendment rights. However, Texas challenged

the ruling and its enforcement, and the court revisited the case many times in the following years.

A final judgment was issued in 1992, but back and forth between Texas and Judge Justice continued until 1999, when Judge Justice acknowledged the state's progress but still found certain areas of compliance deficient. In 2001, the Fifth Circuit Court of Appeals reversed Judge Justice's most recent 1999 opinion, declaring his reasons for not vacating the 1992 final judgment inadequate. In 2002, the Fifth Circuit dismissed *Ruiz*, thus ending Judge Justice's oversight over Texas prisons.

Judge Justice's 1979 ruling was noteworthy as the first case in which a federal court ruled on state prison conditions, a reversal of the prior *hands off doctrine*. *Ruiz* was also unique due to Judge Justice's *judicial activism*: He aggregated individual inmate complaints by topic, found a representative plaintiff for each type of claim, found counsel to represent the plaintiffs, and issued an order for the U.S. Department of Justice to become involved in the litigation. Due to this order, the Department of Justice conducted its own investigation of the TDC prison system, which moved it to join the plaintiffs in their suit against TDC. Judge Justice took these unusual steps to correct what he saw as systematic procedural injustice: Individual inmates without counsel, with poorly presented complaints, had no chance at redress of their grievances when faced with state attorneys representing TDC in court. *Ruiz* was therefore also revolutionary regarding the role of the justice system and judges within it and addressed power imbalances that may hinder inmate claims and the claims of other individuals against powerful systems.

Judge Justice's ruling issued specific and copious directives to TDC to correct its constitutional violations, which was also unheard of in this context. Texas was able to comply with many of Judge Justice's orders, but the problem of overcrowding proved more challenging. Texas sought to comply by reducing prison populations through the use of parole and probation. This contributed to higher rates of violent crime, which resulted in public outcry for the convicted to serve more time behind bars. That backlash, combined with increased convictions due to the War on Drugs, caused prison populations to begin rising again. In an effort to satisfy both the court order and public

demand, Texas constructed more prisons. When the initial rulings were made in the early 1980s, the state had 18 prison facilities and about 25,000 inmates; by the early 1990s, it had constructed 89 new prisons across the state to house over 100,000 inmates.

Despite *Ruiz*, further prison reform litigation efforts were hindered by Congress's passage of the Prison Litigation Reform Act (PLRA) in 1996. The PLRA was intended to prevent what supporters deemed frivolous litigation and judicial activism on the part of judges like Judge Justice. Because federal prison reform cases are based on constitutional violations (the purview of the Supreme Court), Congress could not change the substantive law, but the PLRA rewrote procedures and remedies. For example, among other provisions, it strongly constrained relief that could be granted, required inmates to first exhaust all remedies provided by the prison system before filing a complaint in court, limited damages and attorneys' fees, imposed filing fees that inmates were required to pay, and required district court judges to screen out and dismiss certain complaints without a hearing, often without notice to the plaintiff. Inmate civil rights cases decreased after the passage of the PLRA.

Nevertheless, *Ruiz* serves as an important example of the challenges faced by inmates both in terms of prison conditions and seeking redress for grievances through the justice system and

represents one effort to mitigate the power imbalance between inmates and the prison system that houses them. *Ruiz* is also a crucial part of the context and history of prison reform litigation and resulting federal legislation and can be viewed as either an exemplar of prisoner civil rights litigation or a failed attempt to stem the tide of retributive criminal justice policies that have led to the construction of myriad new prisons and new overcrowding problems.

S

SADISM

Sadism is generally defined as enjoyment derived from inflicting pain or suffering on other individuals. Sadistic acts can involve inflicting physical, verbal, or psychological harm to an individual. The term is typically discussed as it pertains to extreme behaviors, such as those found in criminal and sexual contexts (e.g., serial murderers, serial rapists, sexual sadists). However, sadism can be nonsexual as well, referring to the enjoyment of domination and the cruelty of others. In fact, some have referenced a milder version of sadism, *everyday sadism*, to describe sadistic tendencies that may be normative and characteristic of human nature. This entry explores the history of sadism, the differences between sadism and sexual sadism, and the challenges inherent in the sadistic personality disorder diagnosis.

History

The term *sadism* was originally derived from the work of Marquis de Sade (1740–1814) a French author who wrote about his personal experience of deriving sexual arousal from the physical suffering of others. The first medical description of sadism was observed by Richard von Krafft-Ebing in 1886 in his book *Psychopathia Sexualis*. Krafft-Ebing described sadism as a type of sexual perversion by which an individual gains sexual gratification through cruel acts. Specifically, he

stated that sadism is “the experience of sexual, pleasurable sensations (including orgasm) produced by acts of cruelty” that may “consist of an innate desire to humiliate, hurt, wound, or even destroy others” (p. 109). In 1905, Sigmund Freud described sadism in his book *Drei Abhandlungen zur Sexualtheorie* [Three essays on the theory of sexuality]. He wrote that sadism stemmed from abnormal psychological development in an individual’s childhood. Since these initial writings, there has been a great deal of confusion and ambiguity about how to define and operationalize sadism. Sexual sadism and sadistic personality disorder are two commonly cited diagnoses related to sadism.

Sexual Sadism

Researchers stress the distinction between *sadism* and *sexual sadism*. While *sadism* can refer to physical, sexual, or mental suffering of the victim, the term *sexual sadism* is reserved specifically for individuals whose sexual gratification results from sadistic acts. Importantly, there are some sadists who do not sexually offend, and most sexual offenders are not sadists. Rape has been commonly associated with sexual sadism, given that it involves forcible penetration of a victim. However, not all rapes can be classified as sadistic. Classification systems of rapists typically include a sadistic subtype, which describes offenders who engage in excessive force against the victim in order to achieve sexual gratification.

Furthermore, individuals who commit sexually motivated murders are not necessarily sexual sadists. While sexual sadism may be associated with sexual offenders or sexual murderers, it is a distinct diagnosis.

Sexual sadism was first described in the 1952 edition of the American Psychiatric Association's *Diagnostic and Statistical Manual of Mental Disorders, First Edition (DSM-I)* as a subtype of sexual deviation, though no specific diagnostic criteria were outlined. In the third edition of the DSM (*DSM-III*), published in 1980, sexual sadism was described as a paraphilia (i.e., an abnormal sexual desire). To be diagnosed with sexual sadism, a person must meet one of the following three criteria: (1) the infliction of repeated and intentional suffering on a nonconsenting individual in order to gain sexual arousal, (2) the individual prefers to achieve sexual arousal from humiliation and simulated or mild suffering of a consenting partner, or (3) the individual achieves sexual excitement from extensive, permanent, or potentially fatal bodily injury on a consenting person. The diagnosis of sexual sadism was included in subsequent editions of the DSM such as the *DSM-III-R* (1987), *DSM-IV* (1994), and *DSM-IV-TR* (2000), with some minor changes in criteria across editions.

Published in 2013, the fifth edition of the DSM (*DSM-5*) includes the diagnosis of sexual sadism disorder as a paraphilia. An individual must meet two criteria in order to be diagnosed with the disorder: First, over the span of at least 6 months, the person is sexually aroused by the physical or psychological suffering of another individual, which is present in fantasies, urges, or behaviors. Second, the person has acted on the sexual desires with a nonconsenting person, or the sexual interest causes significant distress or impairment in important life domains.

It should be noted that attempts to operationally define sexual sadism have been largely unsuccessful to date. Various methods of diagnosing sexual sadism including phallometric responses, self-report measures, crime scene data, and rapist classification systems have been found to be unreliable. Therefore, the validity of the sexual sadism disorder diagnosis has been called into question.

Within forensic settings, the prevalence of sexual sadism disorder diagnosis ranges between 2%

and 30%. For sexual offenders who have been civilly committed, the prevalence is less than 10%. The prevalence among those who committed sexually motivated homicide is between 37% and 75%. In regard to gender differences, the majority of those diagnosed with sexual sadism disorder are males. Sexual sadism is believed to persist throughout an individual's life, though the levels of distress or presence of behaviors with nonconsenting individuals may fluctuate over time. Differential diagnoses include antisocial personality disorder, sexual masochism, and substance use disorders. Those diagnosed with sexual sadism are commonly diagnosed with other paraphilic disorders as well.

The concept of sexual sadism is commonly associated with *sexual masochism*, which refers to individuals who are sexually aroused by being humiliated or physically hurt themselves. Sexual masochism disorder is an official diagnosis in the *DSM-5*. The International Classification of Diseases and Related Health Problems, 10th Revision of the World Health Organization describes a diagnosis of *sadomasochism* to describe the process of inflicting (sadism) or receiving (masochism) pain or humiliation as a form of sexual excitation. Sadomasochism in its nonclinical form is often called *bondage/domination sadomasochism*. It must be noted that those who engage in consensual sadomasochistic activities do not necessarily meet criteria for sexual sadism disorder. Sexual sadism disorder is reserved for instances of nonconsensual sadistic acts and those that cause clinically significant distress or impairment in the individual's life.

Sadistic Personality Disorder

In 1987, the *DSM-III-R* outlined the diagnosis of sadistic personality disorder as an appendix for areas for future research. Criterion A stated that the person must display a pattern of cruel and aggressive behaviors starting in early adulthood, which is evidenced by at least four of eight criteria. The eight criteria are (1) physical aggression used to establish dominance over another, (2) humiliating someone in the presence of others, (3) treating someone under his or her control harshly, (4) taking pleasure in the psychological or physical suffering of others, (5) lying in order to

harm another person, (6) using intimidation to get others to do what he or she wants, (7) taking away the autonomy of those they are in close relationship with, and (8) fascination with violence, injury, or torture. Criterion B requires the behaviors from Criterion A be directed toward more than one individual and not be limited to sexual sadistic behaviors.

It is worth noting that none of the sadistic personality disorder criteria in the *DSM-III-R* referred to *sexual acts*; rather, the focus was on a person's desire to dominate others and gaining pleasure from others' pain. The diagnosis was commonly associated with violent and criminal behaviors. Then, in 1994, sadistic personality disorder was removed from the *DSM-IV* due to controversy over the diagnosis. The main controversies surrounded whether the diagnosis was distinct from other personality disorders, whether the diagnosis had adequate validity and reliability, and whether the diagnosis had clinical utility.

Final Thoughts

Nonsexual sadism is a colloquial term that has been difficult to define and operationalize. Within the psychological community, specific diagnostic criteria for sexual sadism have been established, and sexual sadism is commonly associated with individuals who commit sexual offenses or sexually motivated homicide. Further research is needed on both general sadism and sexual sadism to garner a better understanding of individuals who display these tendencies.

SCREENING ASSESSMENT FOR STALKING AND HARASSMENT (SASH)

The SASH is a brief assessment designed to help frontline professionals prioritize stalking and harassment cases for further response. The SASH was developed due to the dearth of frontline assessment tools specifically for stalking, which differs from intimate partner violence in important ways (both the context of the behavior and who it affects). The number and variety of harassment and stalking cases can overwhelm the resources of first responders such as police, victim shelters, and security services. The SASH is designed to help workers in these agencies make informed decisions about prioritization of resources toward cases that are most likely to require additional investigation or management to prevent harm. This entry describes the development and structure of the SASH, its use, and empirical findings regarding its reliability and validity.

Development of the SASH

The SASH was developed by a team of Australian and Swedish clinicians and researchers with expertise in risk assessment of stalking, harassment, and intimate partner violence. Originally called the *Stalking Assessment Screen*, a 15-item version was developed in 2010 from a review of relevant stalking, violence, and intimate partner violence risk assessment literature. When creating SASH items, the authors also considered the content of three existing structured professional judgment risk assessment instruments that were relevant to stalking: the Stalking Risk Profile (SRP), the Guidelines for Stalking Assessment and Management, and the Brief Spousal Assault Form for the Evaluation of Risk. After reliability and validity trials in Sweden and Australia, the instrument was updated and published as the SASH in 2015.

The SASH does not provide a comprehensive assessment of stalking risk. Rather, it aims to accurately identify cases that require no more than a standard frontline response and separate them from cases that may require additional assessment or management to protect the victim. In this way, the SASH can help frontline workers to make evidence-based decisions about prioritizing cases for further attention or referral to specialist services.

Using the SASH

The SASH is a single-page instrument available in English, Swedish, Dutch, German, and Italian, accompanied by a 20-page user guide. The SASH is designed for use by first responders in stalking situations, such as in general and specialist police teams, domestic violence shelters, security or threat management teams, mental health and forensic mental health agencies, and probation or correctional services. No specialist training or expertise is required to use the SASH, though users are recommended to read the guidelines that provide additional information about rating items and developing responses.

The SASH helps to identify cases that are more likely to involve physical violence or prolonged stalking behavior, both of which can be highly damaging to victims. The SASH should be used only in cases where there is evidence of a current pattern of stalking or harassment—that is, a pattern of repeated, unwanted communications or contacts that cause the target apprehension, distress, or fear that occurs outside of an ongoing intimate relationship. The SASH can be used with perpetrators of either sex, when both the perpetrator and target are over the age of 18 years, and where there is no ongoing relationship between them.

Structure of the SASH

The SASH consists of 16 items, 13 scored in all cases, and 3 scored only if the stalker is a former dating partner or sexual intimate of the target. All items are scored as present, absent, or not known. SASH items evaluate the pattern of current stalking behavior, the background of the perpetrator and the perpetrator's relationship with the victim, situational factors that may exacerbate the

stalking, and the current mental state of the perpetrator and victim. The user is required to make a judgment about his or her level of concern based on the number and nature of items that are known at the time of the assessment. Although concern levels should be closely tied to the number of items present, they can be adjusted if there is something unique about the case that warrants greater or lesser concern. The level of concern is recorded as follows:

- Low: Only 1 or 2 items are present. Standard organizational procedures for stalking/harassment cases should be followed.
- Moderate: Several items are present. The case should be prioritized and given an enhanced response.
- High: Many risk factors are present or specific risk factors suggest imminent and/or severe negative outcomes. The case requires an urgent and comprehensive response.

Given the variety of settings in which the SASH can be used, only general guidance on recommended responses for each concern level is provided. Users are instructed to develop specific responses for each concern level that are relevant to their setting.

Reliability and Validity of the SASH

The authors' unpublished development evaluation of the SASH examined interrater reliability from file review of 34 cases, finding significant κ values for all items (ranging from 0.47 to 0.88) and average-level agreement between raters that an item is present or absent of 90% (ranging from 75% to 97%, depending on item). Convergent validity was investigated by comparing SASH results with those of the SRP in 75 cases (SRP completed at client assessment, SASH from file review). SASH and SRP outcomes were significantly and positively related, with approximately 13% of cases resulting in a problematic incorrect outcome, being judged low concern with the SASH but moderate or high risk with the SRP. Predictive validity in a subsample of 37 stalkers was promising, with no stalkers judged low concern having subsequent police charges for stalking over the following 12 months, one third of

moderate concern cases, and just over half of high concern cases.

In an evaluation by the Netherlands National Police published in 2017, the SASH concern level was shown to have a moderate to strong ability to discriminate between stalkers with and without further victim reports to police (area under curve = .68), while interrater reliability was assessed by comparing the results of five police members in five cases. Item ratings were consistent 81% of the time (with variability by item), though reliability of concern judgments was lower, achieving only 59% agreement, which motivated the development of training and translation of the user manual to ensure greater consistency.

SECURE CONFINEMENT

The term *incarceration* connotes confinement in a jail or prison; however, when referring to non-criminal juvenile offenders, the term *secure confinement* is typically used. In all 50 U.S. states,

persons who have not been convicted of—or even charged with—a crime can be placed in secure confinement under civil law. What these persons have in common is that they are children and are under the jurisdiction of the juvenile court. Their secure confinement may take place in facilities called juvenile halls, rehabilitation camps, or state training schools—or even a cottage, camp, or group home. Regardless of the term used for the facility, a minor placed in such confinement—and in some cases even at home with parents—remains subject to the juvenile court's power and, if found to have disobeyed a valid court order, may be incarcerated. This entry reviews the court systems and procedures involved in the secure confinement of noncriminal juvenile offenders.

Jurisdiction

Every state has a specialized court within its judicial system, designed to provide individualized care, custody, and control for children. The juvenile court has broad jurisdiction over children who are found to be *dependent*, *delinquent*, or *status offenders*. Dependent children are those found to be abused, neglected, or abandoned by their parents. A delinquent is a minor who commits an offense that would be criminal for an adult, ranging from a misdemeanor to a felony, including a serious or violent act such as rape or murder. A status offender is a minor who engages in behavior that, although legal for an adult, is unlawful because of the *status* of minority. Examples of such behavior are running away from home, truancy from school, violation of age-specific curfews, and disobedience of parents' reasonable commands.

Parens patriae refers to the state's power to act in the place of parents when necessary to protect children. *Parens patriae* is the basis of juvenile court jurisdiction over status offenders and dependent children and, joined with the state's *police power* to protect public safety, supports its jurisdiction over delinquents.

Due Process

Under the Constitution of the United States, children have a protected right to liberty and privacy, just as do adults. The Fourteenth Amendment

provides that the state cannot restrict or deny these rights without providing *due process of law*. This term encompasses both substantive and procedural due process. *Substantive due process* means that the state has an interest sufficiently important to justify its action and that the means it uses has a sufficient nexus to that interest. For example, the state's interest in preventing child abuse can justify enacting laws prohibiting such abuse and removing abused children from their parents' custody.

Procedural due process requires that the state provide procedural protections to sufficiently reduce the risk of an erroneous decision. At a minimum, this includes notice to children and parents of the state's proposed action and a hearing before a neutral decision maker, at which relevant evidence is presented and legal assistance is provided. The Supreme Court of the United States has ruled that in juvenile court proceedings alleging delinquency, the minor is entitled to most of the same procedural protections as would be provided in an adult court, including a right to counsel and to have the state's allegations proved beyond a reasonable doubt. As of 2018, the Court had not yet ruled on whether a minor has the same rights in status offense cases, and so states vary in the degree of procedural protections they offer. However, it has been argued that the Constitution requires the most stringent procedural due process in any case where the state seeks to deprive the minor of liberty, that is, where there is a risk of secure confinement.

Juvenile Court

The juvenile court is a civil rather than criminal court. To avoid the stigma of criminal conviction, it uses a special vocabulary: instead of arrested, a child is *taken into custody*; instead of the defendant being jailed pretrial, the *minor* is held in *detention* while the *intake officer* and district attorney decide what action to take. Instead of a criminal charge, the state files a *petition* asking the court to *find that it has jurisdiction* over the minor as a delinquent, a status offender, or a dependent. There is no right to bail in juvenile court, but once a petition is filed, the judge decides whether the child should be *detained* in a locked facility such as a juvenile hall, or in a foster home, or released to his or her parents.

Instead of a trial, there is a *jurisdictional hearing* or *adjudication* at which the judge either sustains (grants) or denies the jurisdictional petition. There is no jury in juvenile proceedings; the judge has sole authority to rule on the petition. In most cases, in juvenile (as in adult criminal court), there is no full trial or adversarial hearing; rather, after consulting with legal counsel, the minor enters a plea. The judge finds jurisdiction over the minor based on the plea, and then he or she pronounces not a sentence but a *disposition*. The *disposition* determines the nature and duration of any secure confinement of the child.

The original concept of the juvenile court, first established in Illinois in 1899, was to intervene in the lives of youth seen as *at risk* of a life of crime as adults. The court was created to prevent future criminal conduct through using techniques and providing services to reform and rehabilitate these children. This primary rehabilitative purpose, consistent with the state as *parens patriae*, is still referenced in every state's juvenile code. However, *preserving public safety* is the juvenile court's important secondary purpose, reflecting the state's police power.

Overuse and Misuse

From the outset, the juvenile justice system's emphasis on preventing future crime coupled with inadequate funding and staffing of juvenile programs produced misuse and overuse of secure confinement. In counties where there was no juvenile hall, intake of children took place at police stations and detention in adult jails. Runaway and truant juveniles were placed with serious offenders, who sometimes subjected them to violence. Open-ended disposition laws meant that children found to be delinquent could be confined in prisonlike state training schools for years longer than an adult would have served for the same offense. The conditions in juvenile facilities were often worse than those of their adult equivalents, failing to provide minimally adequate custodial care, much less education and rehabilitative treatment.

In response to these systemic failures, in 1974, the U.S. Congress passed the Juvenile Justice and Delinquency Prevention Act. The Juvenile Justice and Delinquency Prevention Act, which has since been renewed several times, provides financial

grants to states to improve their juvenile systems. As a condition of receiving continuing financial assistance, the states must remove children from all facilities that also confine adult offenders and eliminate secure confinement for dependent children and status offenders. At the time, juvenile court judges and officials agreed in principle that dependent children and status offenders should be separated from adult offenders and delinquents and rarely if ever placed in secure confinement. A range of nonsecure alternative programs would be developed in which dependents, status offenders, and even nondangerous delinquents could be educated and rehabilitated. Secure juvenile halls and state training schools would be reserved only for the most difficult delinquents. By the end of the 1980s, every state amended its juvenile code to comply with the Juvenile Justice and Delinquency Prevention Act's requirements.

However, despite the language of both federal and state laws, in 2018, the overuse of secure confinement for children remains a serious issue. Contributing factors are well-documented by criminologists and social scientists and cited in court opinions and preambles to reform legislation. These include:

- large caseloads and too few case workers, court staff, judges, and attorneys to give adequate attention to each case
- lack of training for court personnel in areas (e.g., child development, behavioral science, substance abuse, family dynamics) needed to make appropriate pre- and posthearing placement decisions
- influence of conscious or unconscious prejudice (e.g., based on race, gender, nationality, or religion) in assessing dangerousness
- political pressure on decision makers to err on the side of confining children to appease public fear of crime
- the lack of less restrictive, alternative programs that enable children to remain in or return to their families and communities

Children placed in secure confinement must be released when they reach the age of majority or when the juvenile court disposition order expires. The court's decision to confine them may have been correct or it may have reflected the

mentioned contributing factors. In either case, consistent with the purpose of the juvenile court, these children have a right to receive appropriate, individualized care, education, and rehabilitative treatment during secure confinement. Without it, each faces a risk of incarceration as an adult offender.

SEGREGATION IN PRISON, PHYSICAL CONSEQUENCES OF

A great deal has been written about the effects of prison life and of special conditions of confinement such as segregation, particularly in regard to mental health. Segregation occurs when an inmate is placed in a cell separate from the general population. However, much less is known about the effects of segregation on inmates' physical health. There are two perspectives on this matter. One is that prison life is stressful and should manifest itself in negative physical health outcomes especially in the case of extreme forms of lockup—like segregation, where inmates are cell bound for 23 hr and experience less cognitive and physical stimulation which may be harmful to their health. Another perspective, however, contends that offenders lead a far more risky life outside the institution; since they have more access to medical services when incarcerated, their health could possibly improve in prison, including in conditions that include segregation. This entry provides an overview of the health-care outcomes experienced by those in segregation, then examines the limitations of the relevant research.

Health-Care Outcomes

The results from primary studies and meta-analyses indicate that life in prison may produce slightly elevated levels of heart rate and blood pressure in inmates when living conditions are crowded. In the case of segregation, the research

indicates a lowering of Electroencephalogram (EEG), to more of a somnolent state, heightened attention to sensory stimuli, and lower stress levels. These reactions are not pathological but rather a natural reaction by the inmate's perceptual system to less sensory input. Thus, at first glance, it seems that segregation does not jeopardize the inmate's health in any significant way. Indeed, it seems that segregation actually lessens stress levels in the inmate.

Methodological Problems in the Research

However, this conclusion is very tentative because of major methodological problems in the research on the physical effects of segregation on inmates. These particular concerns exist with respect to segregation:

- a) To date only a limited number of health variables have been studied and sample sizes are small. Replication of existing studies is critical.
- b) It is quite plausible that health problems seen in segregation exist prior to segregation. Thus, in future studies, evidence of the physical health of the inmate must be gathered before incarceration, during incarceration, before and after being placed in segregation, and upon release.
- c) Evidence is needed about the quality of living conditions (i.e., hygiene, inmates' safety, prison recreational activities, treatment programs, the prison *climate*, abrupt changes in population, management practices) and the quality of health care in the prison. Prisons that do not meet adequate standards/practices in this regard likely will produce negative results that cannot be attributed to segregation per se.
- d) Individual differences that may be associated with health care have yet to be studied. These include inmate demographics (e.g., age, race), risk level, and personality factors (e.g., temperament).
- e) Higher rates of self-injury and suicide are found in segregation, but it is quite plausible that these findings are due to selection factors. Inmates with self-harm behavior have more misconducts and as a result are placed in segregation. Much needed research remains to be done in this area.

Only when these methodological issues are addressed will it be possible to ascertain a complete picture of the effects of segregation on inmates' physical health.

SEGREGATION IN PRISON, PSYCHOLOGICAL CONSEQUENCES OF

Each year in the United States, approximately 80,000 justice involved individuals are placed in segregation (i.e., housed separately from the general prison population). Although the practice occurs frequently, ongoing debate exists as to whether it is humane, whether it exacerbates mental health problems in justice involved individuals, and whether it is an effective punishment to modify problematic institutional behavior. Research oscillates between concluding whether segregation is an inhumane practice associated with a wide range of negative psychological and physiological effects and whether it is a humane practice that does not result in long-term negative psychological and physiological consequences for justice involved individuals. However, recent research concludes that segregation does not produce lasting emotional damage, but it also does not modify or decrease problematic behavior. It is possible that short-term segregation may not be any more harmful than the overall experience of being incarcerated. To assist

policy makers' decisions regarding whether the practice of segregation should continue to be used, there is a need to examine the psychological effects of segregation as it relates to long-term or short-term use, preexisting individual mental health conditions, institutional adjustment, and recidivism.

It is important to note that a large percentage of justice involved individuals already have existing mental health problems upon incarceration. Segregation can contribute to psychological effects, including emotional, cognitive, and psychosis-related symptoms. Research indicates long-term segregation of justice involved individuals with serious preexisting emotional and behavioral problems can exacerbate their mental health symptoms. For some justice involved individuals, it is possible that long-term segregation is harmful to their mental health, particularly psychosis, because it restricts meaningful social contact, which is essential for healthy human functioning.

It can be argued that segregation is counterintuitive because the lack of social connectedness and social support contributes to poor institutional adjustment in justice involved individuals with already existing mental health problems. Long-term segregation has been linked to institutional adjustment problems both during and after confinement including increase in prison misconduct and increased hostility toward correctional officers. Research suggests justice involved individuals adapt to the segregation environment by changing their patterns of thinking, acting, and feeling to accommodate the isolation and rigidity of living in segregation. After placement in segregation, justice involved individuals may become uncomfortable with even small amounts of freedom because they have lost the sense of how to behave in the absence of constantly enforced restrictions, tight external structure, and the ubiquitous physical restraints.

Although the practice is highly criticized, other research has identified a psychopathological condition, known as *segregated housing unit* syndrome. The effects of segregated housing unit syndrome have been associated with specific psychiatric symptoms including the following: hyper-responsivity to external stimuli; perceptual distortions; illusions and hallucinations; panic attacks; difficulties with thinking, concentration, and memory; intrusive obsessional thoughts; overt

paranoia; and problems with impulse control. It can be argued that individuals with preexisting mental health problems and a longer duration in segregation would experience the segregated housing unit syndrome more severely.

In addition to already discussed psychological effects, research suggests rates of self-harm and suicide are more common in segregated justice involved individuals as compared to non-segregated justice involved individuals. Research examining a Canadian prison sample of 967 justice involved individuals reported that 86.6% who had a history of self-injury also had a history of segregation, as compared to a rate of 48.1% in the general population. Interestingly, close to one third of the reported self-harm incidents in the sample occurred in segregation. Furthermore, several researchers have concluded the literature is clear that short-term and long-term segregation can increase the risk of suicidal behavior.

Finally, warranting further consideration is the research reporting justice involved individuals who spent time in segregation have higher rates of recidivism. Researchers have attempted to answer why segregation contributes to future offending and hypothesized the psychological and behavioral effects of increased anger, hostility, aggression, and lack of opportunity to learn prosocial ways of self-regulation act in a criminogenic (causing crime) fashion. However, controlling for risk of recidivism would be important in examining the relationship between the psychological effects of segregation and recidivism, institutional behavioral problems. Within higher risk individuals, it is possible the effect becomes stronger with longer periods of segregation.

In summary, research concluding segregation does not contribute to serious long-term psychological effects is based on samples in which placement in segregation was less than a year. It is important to further examine the impact of longer term segregation and environmental factors (e.g., overcrowding, prison subculture including relationship between staff and inmate) on the psychological and behavioral well-being of justice involved individuals. It is possible under certain prison environmental conditions segregation may contribute to more serious psychological pathology than that produced by incarceration alone.

However, research conducted in 2016 suggests segregation may not contribute to psychological harm in the majority of justice involved individuals and the case that it does for some may be overstated. It is possible identifying for which justice involved individuals the use of segregation may have psychological impact may be where the field needs to move instead of abandoning the use of segregation altogether.

SEGREGATION IN PRISONS

Although first implemented in the late 1700s as a measure of criminal justice reform, contemporary prison segregation is an increasingly popular, yet contentious, correctional practice aimed at containing difficult-to-manage behavior that

threatens institutional safety and management. High-security housing blocks designed to separate at-risk and problematic inmates from the general prison population are referred to by a variety of names depending on the institution, including administrative segregation (AS; *ad-seg*), special housing units (*the shoe*), special management, and restrictive housing. Although less often used in an official capacity, segregation is also commonly described as solitary confinement or *the hole*.

Despite the interchangeable use of these labels, there are two general types of segregation used in most U.S. correctional facilities: disciplinary segregation (DS) and AS. DS typically refers to the use of segregated housing as a punishment for a specific incident of rule-violating behavior. The duration of DS is usually specified in advance (e.g., 7 days, 30 days) and is determined based on the severity of the misconduct or its consequences. AS is typically associated with indeterminate placements (i.e., the detainee's release date is unknown) and is primarily used to reduce the risk of harm to the inmate or others. Among other things, an inmate may be placed in AS as a result of repeat violent or riotous behaviors, having an escape history or being at risk of escape, expressing suicidal ideation or gestures, identifying as a sexual or other minority prone to discrimination, or being a known or suspected gang affiliate. It is not uncommon for AS inmates to spend years in these restricted units. Regardless of how an inmate gets to segregation or whether her or his time is made explicit or not, DS and AS terms tend to be carried out under similar conditions.

This entry provides an overview of segregation in prisons, including its history in the United States, the contentious debates surrounding its use as a correctional practice, and its effects on inmates' well-being.

History of Prison Segregation in the United States

Prior to the late 1700s, crimes were punished based on the eye-for-an-eye philosophy, and sentences were served in the form of public humiliation, torture, and death by hanging. However, around the turn of the century, the Quakers—a Christian sect that dominated the American

colonies—began a revolution in criminal justice advancement and reform. The Quakers set out to establish a more organized penal system that focused not on punishment, but on rehabilitation. By introducing wrongdoers to puritan values, such as piety and work ethic, the Quakers believed that anyone, no matter how evil the act, was capable of positive change and spiritual growth. While the Quakers have been praised for this progressive view of incarceration, they were also responsible for initiating a prison practice that today has become regarded by many scholars and human rights activists as cruel and inhumane. The Quakers first used isolation (reportedly in 1790 at the former Philadelphia Walnut Street Jail) as a means to reform and manage prisoner behavior. At the time, this practice was seen as consistent with the overall goal of rehabilitation, as it was intended to provide offenders with the quiet solitude necessary to think about the consequences of their behaviors, repent to God and seek His forgiveness, and eventually emerge as a changed person. Except when working hard labor, inmates were expected to abstain from conversing at all times—a Quaker principle known as *quietism*—and were held in private cells with minimal activity or resources other than silent prayer and a copy of the Holy Bible.

In the 1820s, Pennsylvania carried on the Quaker tradition of isolated repentance and built what is now considered to be the first state-of-the-art prison structure, Eastern State Penitentiary. The penitentiary, which included only solitary cells, came to house some of America's most violent and notorious criminals, including several stints by the well-known prohibition gangster Al Capone. With prison expansion, the incarceration pendulum began to swing back in favor of punishment, and solitary confinement quickly moved from a place of atonement to a place of torment and containment. Inmates were subjected to small, dark, and filthy rooms with little sensory stimulation or human interaction beyond occasional visits from reverends or prison guards. Anecdotal reports of the times described men who became *violently insane* or resorting to suicide as a result of enduring lengthy periods of time in complete isolation. In 1890, Supreme Court Justice Samuel Freeman Miller (134 U.S. 160) expressed concern about the negative consequences of isolation and

noted that prisoners did not appear to be reformed through the process.

Despite growing opposition and activism in response to the maltreatment of inmates held in segregation units, the use of isolation as a method of punishment and behavioral control has persisted across the United States. In addition to continued establishment and maintenance of segregation blocks within prisons, the mid-1990s also saw a surge in the creation of the so-called supermax facilities (e.g., Federal Administrative Maximum Facility in Florence, Colorado) that, such as Eastern State Penitentiary, only operate restricted-access cells. By 2005, at least 40 states were running a supermax prison. In 2014, a national survey published out of the Yale University School of Law estimated that nearly 80,000 to 100,000 inmates were being held in segregated housing. However, this survey was likely an underestimate, as it did not include local jails, juvenile facilities, or military and immigration detention centers. These numbers suggest that, as of 2016, the United States was not only the prison capital of the world, but also the leader in implementing segregation practices.

Today, the conditions of segregation look a bit different from those in the early days of the Quakers and Eastern State Penitentiary, yet diminished interpersonal contact and restricted activity remain key features. In most modern correctional institutions, segregated inmates are confined in their cells (usually alone, but sometimes with a cellmate) from 22 to 24 hours a day with approximately 1 hour allocated to exercise or shower each day. Other facilities may only permit showers 3–4 days of the week. Recreation time is generally conducted in individualized, fenced-off, outdoor areas that are maintained within the segregation block. Meals, medications, mail, and other properties are delivered to inmates through a slot in their metal cell door (this slot is also used to handcuff inmates prior to the release from their cell). All segregation units, regardless of the facility, closely monitor inmate movement and may limit access to mental health programming, educational classes, religious services, the library, personal possessions, and physical exercise.

However, it is important to recognize that the isolation experience can differ substantially depending on the criteria and policies established by the

facility. Segregation can range from an inmate being completely locked down and dressed in security clothing with no sources of entertainment (e.g., during crisis or suicide watch), to a relatively active area with a variety of material possessions. Most U.S. Department of Corrections, for example, allow segregated inmates to receive mail call, visitations, commissary, and telephone privileges on a restricted basis, as well as in-cell access to reading materials, stationery, and art supplies. On the basis of good behavior and personal finances, in some jurisdictions, inmates may be permitted to have private radios or televisions.

The Great Segregation Debate

The use of segregated housing as a correctional practice became a hotly debated social and criminal justice issue. As the war between proponents and opponents waged on, three theoretical perspectives emerged, each offering differing predictions about the effects of prison segregation. The first perspective is grounded in the long-standing *tough on crime* mentality in the United States that advocates that prisons should be an adverse experience and that the more severe the punishment, the greater the impact it will have on deterring future criminal activity. Prison policy makers who support this general position see segregation as a useful punisher that suppresses antisocial behavior in prison and, eventually, postrelease.

In contrast to the *get-tough* approach, the second perspective holds that segregation causes undue psychological stress to inmates, so much so that it becomes a form of torture. Thus, rather than deterring crime, segregation essentially breaks down the psyche of those detained there and may lead to worse behavioral and emotional consequences. Some scholars and activists have postulated that even short periods of isolation (e.g., from 3 to 90 days) can result in long-term psychological damage, cognitive impairment, and psychosis. Therefore, segregation should be abolished. Abolitionists see no rehabilitative effect of segregation and strongly contend that placement in these units does disproportionately more harm than good. As a result, concerns about the inhumane treatment of segregated inmates triggered a number of lawsuits across North America (e.g., Canadian Human Rights Tribunal, *Desmarais v.*

Correctional Service Canada, *Madrid v. Gomez*, *Ashker et al. v. Governor et al.*, *Silverstein v. Federal Bureau of Prisons*).

The third perspective borrows from the idea that prisons create a behavioral deep freeze, meaning that life behind bars does not in fact worsen an offender's behavior. In the early 1990s, Canadian prison researchers Don Andrews and Paul Gendreau proposed that the prison environment, including long-term segregation, produces less intense psychopathology than previously believed and that much of the maladaptive behavior the inmates display in prison existed well before their incarceration. This idea assumes that the general conditions in prisons meet basic standards of humane care. Those who ascribe to this position point to other factors operating within the prison milieu (e.g., managerial policies, how inmates across the institution are treated by staff), as the more direct cause of observed and reported iatrogenic consequences rather than segregated placement itself. That is, the negative effects attributed to segregation are, in actuality, due to broader systemic and/or preexisting conditions. These researchers, and others in their camp, argue that the impact of prison segregation on offender well-being has been generally overstated and largely unsupported in the empirical literature (to be reviewed next). In fact, it has been suggested that the transition from community to prison is incrementally more challenging than the transition from general prison population to segregation.

Effects of Segregation on Prisoner Well-Being

The topic of prison segregation has always been a rather contentious issue; however, the argument over its use gained momentum around the 1950s (notably, over 150 years after its conception) with the emergence of some dramatic results—allegedly funded by the U.S. Central Intelligence Agency—stemming from research in the field of sensation and perception on the effects of confinement as a psychological interrogation technique. This research was directed by neuropsychologist Donald Hebb and psychiatrist Donald Cameron (the latter of whom was infamously known for his process of *de-patterning the mind*, which involved large, repeated doses of electroconvulsive shocks

combined with psychedelic drugs as an attempt to alter behavior).

Attracting particular attention were Hebb's sensory deprivation (SD) experiments in which sensory input (e.g., light, sound) in the environment was restricted. Typically, findings showed that participants' cognitive and perceptual abilities deteriorated markedly, even after just 1 hour of deprivation. Acceptance of these findings persisted into the late 1960s until they were challenged by a number of researchers who demonstrated that uncontrolled experimenter and setting dynamics introduced response bias in the early SD studies. For example, Martin Orne and other skeptics argued that Hebb's SD studies were confounded by demand characteristics, such that participants exhibited symptomology consistent with SD because they knew or guessed the expected results.

An interest in SD influenced later research by Peter Suedfeld and colleagues beginning in the mid-1970s. In 1975, Suedfeld summarized the effects of SD to date following a review of extant studies involving more than 3,300 participants with varying backgrounds. Through this work, he concluded that "one rarely finds, particularly in more recent studies, extreme emotionality, anger, and anxiety" (p. 62). Suedfeld went on to objectively study the effects of solitary confinement on incarcerated offenders. In a well-known study published in 1982, Suedfeld and his team collected inmate self-report data on mental health functioning (e.g., measures of personality, mood, stress, creativity, and intelligence) from five institutions across the United States and Canada that operated segregation units. Increased time in solitary confinement was associated with higher levels of inhibition, submissiveness, depression, anxiety, and hostility. However, the findings also highlighted the variability in inmate reactions to solitary confinement. That is, some inmates reported extreme stress, others reported their experience as unpleasant but tolerable, yet others found it relaxing and considered it as an opportunity for contemplation and self-reflection. These researchers thus concluded that solitary confinement is not universally damaging, aversive, or intolerable and that the symptoms experienced by inmates in solitary confinement were not significantly different from those of prisoners in the general population. This finding seems

to support the perspective of Andrews and Gendreau that prison segregation in and of itself is not damaging to inmates' well-being. Suedfeld's 1982 study was replicated by Ivan Zinger in 2001 (nearly 20 years later) and showed similar results.

Contrary to the work of Suedfeld, Stuart Grassian, who was conducting research around the same time, came to a much different conclusion following a study involving 14 inmates who were part of a class action lawsuit alleging violations of the Eighth Amendment to the U.S. Constitution (protection against cruel and unusual punishment) in relation to their placement in solitary confinement. Grassian interviewed each inmate individually and identified a cluster of symptoms that have since been coined as the special housing unit syndrome. Aversive symptoms reported by inmates in Grassian's 1983 study included perceptual changes (e.g., hypersensitivity to external stimuli, distortions, hallucinations, paranoia, and derealization experiences), intense anxiety, cognitive difficulties (e.g., thinking, concentration, and memory problems), loss of impulse control, and aggressive thoughts of revenge, torture, and mutilation of the prison guards. However, Grassian's study also showed a rapid drop in symptom breadth and severity upon release from isolation. Furthermore, the study contained several noteworthy limitations. In addition to the small sample size, only inmates who were involved in the lawsuit (which was ongoing at the time of data collection) were interviewed, and all interviews took place at inmates' cell doors where they may have been more likely to disclose information supporting the claims made in the lawsuit. Thus, the participants had a conflict of interest that likely biased their responses.

Since Grassian's study, other research supporting the negative effects of segregation has emerged. Largely spearheaded by Craig Haney, it has been suggested that psychological symptoms such as anxiety, paranoia, depression, and perceptual distortions of inmates are exacerbated by the conditions of restricted confinement. In addition, individuals with preexisting mental disorders, who appear to be overrepresented in segregation because their odd or disruptive behaviors are seen as otherwise unmanageable, are arguably at the greatest risk of more permanent and disabling adverse effects. A 2007 study by David Lovell and

colleagues showed that inmates released directly from segregation to the community had higher rates of recidivism than those not released directly from segregation. Furthermore, despite the intention to reduce incidents of self-harm, several studies in the 2010s found that segregated inmates engaged in these behaviors (including suicide attempts) at higher rates compared with those detained in the general population. Despite Grassian's earlier finding that the effects of solitary confinement are quickly remediated upon release, some scholars have since suggested that longer periods of exposure to segregation may be associated with more lasting psychological changes. Thus, many researchers in this school support the perspective that segregation is psychologically debilitating and a form of torture.

However, most studies on prison segregation and solitary confinement generally lacked scientific integrity and varied widely in their methodology and data collection procedures. For example, the majority of the existing studies evaluated data retrospectively rather than assessing psychopathology before and after segregation was imposed. Similar to the criticisms of Grassian's 1983 study, many subsequent studies also used small sample sizes that were not generalizable across other segregated populations or institutions. Other shortcomings in the literature were again attributed to methodological issues such as selection bias, qualitative outcomes, and failure to control for response bias when the inmates would benefit from secondary gain by reporting or denying symptoms.

In the Colorado Department of Corrections, Maureen O'Keefe and her research team perhaps conducted the most methodologically sophisticated study on the psychological effects of prison segregation to date. O'Keefe and colleagues compared inmates detained in AS, the general prison population, and a psychiatric correctional facility on mental health functioning. Inmates were assessed after 1 year of incarceration on various symptom categories (i.e., psychosis, anxiety, depression, hopelessness, somatization, social and cognitive functioning, anger, and hypersensitivity). The results revealed that individuals in AS were not statistically significantly worse off than their study counterparts. Furthermore, only 7% of inmates in AS reported an increase in psychological

symptoms. Interestingly, 20% improved and the remaining participants were unaffected after the 1-year period. However, this study had limitations of its own. For example, only inmates who had 1 year or less in AS were included in the study. As was mentioned earlier in this entry, AS inmates have been known to spend years or even decades in confinement.

Some 30 years after Suedfeld's and Grassian's initial studies, researchers, policy makers, and the general public remain divided on whether or not (and to what extent) the use of prison segregation is psychologically, emotionally, and socially damaging to the well-being of prisoners. In a 2016 attempt to clarify the effects of segregation, Robert Morgan, Paul Gendreau, and their colleagues undertook two independent meta-analytic reviews (published together) and reported small to marginal effects across most physical (e.g., sensory arousal), behavioral (e.g., prison misconducts), and mental health (e.g., mood, anxiety, anger/aggression, psychosis, and hypersensitivity) outcomes. Consistent with Suedfeld's declaration decades earlier, the authors concluded that the adverse effects of segregation appear to be overstated; however, in light of several limitations within the literature base (primarily those noted earlier), they advocated for additional research to confirm the problems (or lack thereof) associated with segregated placement. Specifically, research that employed pre-post testing to account for baseline functioning and included inmates with longer segregation sentences was greatly needed.

Segregation Moving Forward

Regardless of which side of the argument people fall on, most would likely agree that segregation is not the best method for dealing with young offenders or the severely mentally disturbed and that its use should be limited to the extent possible. In fact, in January 2016, President Barack Obama issued a statement calling for a significant reduction in the use of segregation to punish prisoners and restrict their access to rehabilitative services. Perhaps prison segregation does have a purpose in the U.S. prison system, but perhaps it is also time to rethink that purpose. That is, rather than serving as an idle place to contain bad

behavior, it may be more productive to view segregation as an opportunity for disruptive and/or disordered inmates to focus on positive growth. While this proposition sounds similar to the ways of the Quakers, the delivery of evidence-based step-down programming (rather than strict religious practices) within the context of humane housing conditions and hope for release could prove beneficial. Certainly, prisoners should be continually monitored by mental health staff for behavioral changes, with those evidencing physical or emotional decompensation transitioned out of the unit for further care.

SEGREGATION IN PRISONS, ADMINISTRATIVE

Administrative segregation—also known as *solitary confinement*—involves the housing of an inmate in conditions characterized by substantial

isolation from other inmates. The use of administrative segregation in the United States has risen precipitously since the 1980s, as have concerns about its effects and utility. Some claim that administrative segregation is a necessary tool for managing correctional populations, while others insist it is an overused management strategy that produces many damaging effects on inmates and staff. The use of this correctional practice not only raises empirical questions but also moral, ethical, and legal concerns. This entry focuses on some of the current issues surrounding the contemporary use of administrative segregation in the United States.

Administrative Segregation

The historical origins of administrative segregation in the United States can be traced to the silent penitentiaries in early 19th century, where inmates were subjected to very extreme forms of social isolation and sensory deprivation. Things changed in the 1980s when several *get tough* penal policies were enacted, which led to a significant increase in the number of incarcerated offenders (e.g., mandatory minimum sentencing laws, three-strikes laws, War on Drugs). During this time, overcrowded living conditions and increased institutional violence led to growing concerns for staff and inmate safety in prison. In response, many correctional officials across the United States increased their reliance on segregated confinement as a means to ensure reductions in violence and other serious disruptions within the prison system.

The modern use of administrative segregation includes the removal of inmates who are suspected of posing a threat to the well order of the institution from the general prison population. This includes those inmates who have demonstrated an inability to adjust to the general population or those whose presence in the general population is believed to likely seriously disrupt the orderly operation of the institution. There is a widely held belief among policy makers and corrections officials that the use of administrative segregation is an effective risk management strategy for increasing safety and promoting order throughout the prison system. However, those critical of the practice contend that the use of administrative

segregation raises constitutional and humanitarian concerns, and charge the practice constitutes cruel and unusual punishment, is inhumane, and violates the minimum standards of decency.

Conditions in Administrative Segregation

The conditions in administrative segregation have often been characterized by intense isolation and absolute control. Prisoners housed in these settings are typically confined to a single cell for up to 23 hr of the day and are further subjected to increased cell restrictions and heightened security procedures. These prisoners are granted limited access to education, vocation, visitation, recreation, and other services that are available to the general prison population. Prisoners in segregation are often taken out of their cells for only 1 hr per day, usually for a shower or exercise. Recreation in many administrative segregation units takes place in a small fenced area that is exposed to the weather. Likewise, prisoners must choose whether to go into these exercise areas during extreme weather conditions or remain in their cells and take no out-of-cell exercise for the day. Before leaving their cell for any reason, inmates are usually handcuffed, and, sometimes, they are even shackled at the waist and placed in leg irons.

Inmates in administrative segregation must eat, sleep, and go to the bathroom in their cells. Food is delivered through a slot in the door, meetings with counselors and mental health providers are often conducted through the cell door, and exercise is taken alone. Visits are often restricted and can be prohibited for a certain period of time when the inmate first arrives in the administrative segregation unit. When family visits are allowed, the interactions are generally conducted via a telephone, and the visitor and the inmate sit on separate sides of a thick glass window. Finally, even mental health and medical services are extremely limited for prisoners in segregation, which further reduces their opportunity for human contact.

The Use of Administrative Segregation

Administrative segregation is often enforced for indeterminate periods of time. In some systems, inmates are not told the reason for their transfer to administrative segregation, and options for

reevaluation or release back to the general prison population may be few. For those inmates considered to be a continued threat to safety and security of the facility, segregation may be imposed for very long periods of time. Several studies in the 2010s reported that inmates are placed in such settings for durations ranging from fewer than 30 days to several years. In some cases, inmates are held in segregation until they are discharged to the community at the expiration of their sentence.

It has been difficult to obtain reliable prevalence estimates of the use of administrative segregation in the United States, particularly because many jails and prisons do not track this information in a way that can easily be accessed. Likewise, previous estimates have varied widely from 20,000 to 100,000. The extent of the use of segregation also appears to vary widely among states. In a 1998 survey of state departments of corrections, some organizations (e.g., Pennsylvania) reported incarcerating less than 1% of inmates in such settings, while others (e.g., Mississippi) reported incarcerating up to 12%. However, as definitional and reporting issues have been well-documented, in all likelihood, these estimates are low. In a 2015 report conducted by researchers from the U.S. Bureau of Justice Statistics, it was estimated that approximately 18% of jail and prison inmates in the United States spent time in a restricted confinement setting in the previous year. However, it should be cautioned that this estimate includes inmates in segregation for both administrative and disciplinary reasons.

Inmates in Administrative Segregation

Administrative segregation is often described as targeting those inmates deemed to be the *worst of the worst*, which includes those belonging to certain groups such as escape risks, gang members, predators, and high-profile or notorious inmates. This practice has also been highly criticized for segregating a higher proportion of mentally ill inmates and those with developmental disabilities. A review of the available literature reveals that inmates who are placed in administrative segregation settings tend to be younger, more likely to be an ethnic minority, have a mental disorder, be a member of a gang, as well as be rated as high risk to recidivate when compared to

inmates from the general prison population. Administrative segregation inmates are also found to be more likely to have a violent criminal history, have prior juvenile justice involvement, and be rated higher risk on their initial institutional classification rating. Finally, inmates in administrative segregation are also more likely to have been found guilty of an institutional misconduct and have previously served time in segregation.

The Effects of Administrative Segregation

There are three schools of thought on the effects of administrative segregation. The first position—which appears to be the conventional wisdom among prison wardens—suggests the use of administrative segregation increases safety, order, and control in prisons. In contrast, a second school of thought insists that administrative segregation causes serious psychological and other health problems as well as increases criminogenic risk. Finally, a third perspective contends that under conditions in which segregated confinement meets the standards of humane care, relatively few inmates are adversely affected. This position maintains that there are other factors (e.g., how inmates are treated) in the prison environment—beyond simply being confined in a segregation setting—that have more dire consequences.

Despite its long history of use and increase in attention, administrative segregation has remained an elusive subject of empirical research. Within the available administrative segregation literature, the most contentious debates have been around the psychological effects of the setting, although more recently an increased amount of attention has been given to what effect the setting may have on behavioral outcomes (e.g., institutional behavior, postrelease recidivism).

The belief that segregated confinement causes psychological damage is not new. In fact, after visiting some of the early U.S. penitentiaries in the 19th century, several notable European contemporaries condemned the practice, suggesting that the setting caused its inhabitants undue psychological distress. Beginning in the mid-1980s, there has been an increased amount of scholarly attention given toward the study of administrative segregation. The majority of the available research conducted to date has been qualitative in nature and

has generally involved interviews with inmates and mental health professionals in segregation settings. As a group, these anecdotal reports have tended to use powerful excerpts from these interviews in order to suggest that administrative segregation violates prisoners' constitutional rights, contributes to psychological problems, increases criminogenic risk, and is used excessively in the United States. Subsequently, there has become a strong consensus in the literature, as well as a growing public sentiment, that administrative segregation is responsible for producing these devastating effects.

Other scholars, however, have pointed out that much of the literature from which this conclusion is based suffers from many serious methodological limitations (e.g., selection bias, response bias, inadequate or no control groups), which in their estimation should limit the types of conclusions that should be drawn from this research. Two meta-analytic reviews on this topic have found that not only has administrative segregation been an elusive subject of empirical research but also that the effects found from the available studies tend to be *small to moderate*, rather than *large* as has been predicted by those critical of the practice. Despite these disagreements in the interpretation of the available literature, there is clearly a need for more empirical research in this area.

The Future of Administrative Segregation

The primary purpose reported for the use of administrative segregation is that the practice increases system-wide order, safety, and control. However, there is little evidence available that supports these settings are effectively achieving these goals. Recently, there has been a strong consensus in the literature, as well as a growing public sentiment, that the experience of administrative segregation, especially in long durations, is responsible for producing serious psychological problems. It has been these perceived negative effects that have helped make this practice an issue of national attention. Many have argued that given the substantially greater costs associated with administrative segregation that the onus ought to be on those that continue to advocate its use to produce evidence of its benefits. Several efforts have been made recently to reduce the

number of offenders in administrative segregation, particularly for those subpopulations of the mentally ill, juveniles, and women offenders. One of the challenges for ensuring that such reductions will occur is to develop safe alternatives to segregation—and several attempts are currently underway across the country.

prevent high-risk, justice involved individuals from escaping, protect these individuals from harming others, or as a disciplinary response for behavioral misconduct within jail or prison settings due to punishment or protective custody. Through the years, in the United States, litigation at the state level has prompted a call for reform leading to a decrease in the use of segregation. Studies from states that have reduced the use of segregation have found no increase in violence and in some cases experienced a decrease in institutional violence. Those states have also saved more money because of how costly segregation is for the facility. These savings can be invested in other programs that can prevent the need for segregation, such as education and employment programs, drug treatment, and rehabilitation.

For example, in 2009, Mississippi's segregation unit had inhumane living quarters with little impact on inmate behavior. A step-down unit was created as an intermediate-level treatment program to move inmates from segregation back to the general population. The program provided treatment to offenders with a serious mental illness who were required to still be segregated, but not for 23 hr a day, thus allowing more movement and access to activities. The group program was implemented in phases and provided psychoeducation about mental disorders and coping skills in an effort to increase the sense of community and interconnectedness. This program's implementation yielded positive outcomes, including a decrease in the use of force by staff as well as violent offender institutional misconduct. Rule violation reports per offender also decreased from 4.7 to 0.6 per inmate 6 months after release from the step-down program. Offenders are now requesting to participate in the program offered in the segregation step-down unit. This entry discusses how to best use the practice of segregation in prison settings.

SEGREGATION IN PRISONS: BEST PRACTICES

Segregating inmates is an overused practice to manage problematic offender behavior. *Segregation*, also known as *solitary confinement* or *administrative segregation*, is the isolation of an offender in a separate cell. It is commonly used to

Segregation Policy Review

In 2015, President Barack Obama ordered a review of segregation practices in the United States. The review attempted to answer how, when, with whom, and why segregation is used in U.S. prisons. It also worked to develop and implement best practice strategies to reduce the use of

segregation. After completion of the review, it was determined that there are times when segregation must be used to ensure the safety of involved individuals, staff, the institution, and the public. However, when it must be used, it should be done so in a safe, humane manner; serve a specific penological purpose; and be imposed only for as long as necessary to accomplish that purpose.

Based on a review of 47 jurisdictions, including 46 states and the U.S. Federal Bureau of Prisons, five *purpose-based* categories of segregation were identified. These are:

- 1) *investigative segregation*—immediate nonpunitive placement of an inmate in restrictive housing, while officials attempt to determine whether longer term segregation is appropriate;
- 2) *disciplinary segregation*—An offender is placed for a determinate period of time as a punishment for violating a specific institutional disciplinary rule;
- 3) *protective segregation* (or *protective custody*)—An offender is placed to protect him or her from a real or perceived threat within the correctional facility;
- 4) *preventative or administrative segregation*—An offender is placed for an indeterminate amount of time to prevent him or her from threatening the safety and order of the correctional facility; and
- 5) *transitional segregation*—An offender is placed for a nonpunitive and indeterminate, although brief, period of time awaiting a transfer to a new location.

Not all correctional systems use all (or any) of these terms. The lack of consistent definition of what constitutes the purpose of segregation makes it difficult to suggest a standardized set of best practices or alternatives to the use of segregation.

The review articulated guiding principles to direct the development of best policy segregation practices in a report called U.S. Department of Justice Report and Recommendations Concerning the Use of Restrictive Housing. It is suggested when a correctional facility lacks the resources, staffing, or legal authority to implement the

guidelines, a clear plan for building the necessary infrastructure to implement the guidelines should be developed.

Massachusetts implemented the recommended policy changes and decreased their overall population in segregation to 1% of the total population of inmates. Other states generally have at least 3% of their populations segregated. Success in implementing policy change was related to shifting the mindset of the correctional officers in how they use segregation. The use of segregation is considered a last resort, rather than a default solution, for problematic institutional behavior. The correctional cultural shift occurred as a result of far-reaching reform that engaged the entire correctional workforce in the implementation of the reforms.

Policy Recommendations

Correctional facilities should develop clear, specific policies for determining under what conditions an offender is placed in segregation. However, offenders should always be placed in the least restrictive environment necessary to ensure their own safety, as well as the safety of staff, other inmates, and the public. When an offender is placed in segregation, the specific purpose (investigative, protective, disciplinary) should always be documented and supported by objective evidence. Duration in segregation should be no longer than necessary to address the documented purpose. Placement in segregation warrants ongoing review of the offender by a multidisciplinary team, including the leadership of the institution, the medical team, and mental health staff. Upon placement in segregation, a clear and individualized release to a least restrictive environment should be developed and ideally shared with the offender. Offenders in segregation should have access to time outside of the prison cell, confidential psychological services, and visits whenever possible. Segregation units should always maintain adequate conditions to ensure environmental, health, and fire safety as well as basic human needs.

An inmate should not be placed in investigative segregation unless the inmate's alleged offense, or his or her presence in general population, poses a danger to the inmate, staff, other inmates, or the public. In making this determination, officials should consider the seriousness of the alleged

offense, including whether the offense involved violence, escape, or represents a threat to institutional safety. Correctional staff should complete their disciplinary investigation as quickly as possible and any time an offender spends in investigative segregation should be credited toward the amount of disciplinary segregation. An offender's initial placement in investigative segregation should be reviewed within 24 hr by an appropriate security staff member not involved in the initial segregation placement decision.

Offenders who engage in institutional misconduct and violate disciplinary rules should be placed in disciplinary segregation as a last resort when it has been determined other available sanctions are insufficient to serve the purposes of punishment. Segregation should be applied consistently with behavioral principles in a manner that is swift, certain, and fair. Correctional staff should complete the disciplinary investigation as quickly as possible. Any time spent in investigate segregation is credited toward time spent in disciplinary segregation.

When offenders require protection, segregation should only be used when transferring the threatened offender to the general population of another institution or to a special-purpose housing unit for offenders who face similar threats. When the offender is transferred for protective reasons, the offender's reentry community should be considered. Regular review of offenders in preventive segregation should occur with the goal of transition back to a less restrictive environment as soon as possible. For example, offenders in preventive segregation should be given the opportunity to participate in programming or step-down units that facilitate placement in a less restrictive environment.

Offenders with serious mental health problems should not be placed in segregation unless an immediate and serious danger is present and there is no other reasonable option. A qualified mental health professional must determine immediately whether the offender is at risk of suicide and whether he or she possesses any active psychotic symptoms. Offenders with serious mental illness in segregation should receive intensive, clinically appropriate mental health treatment until released from segregation. At least once per week, a multidisciplinary committee consisting of correctional staff and mental health staff should review the

need for segregation and engage in face-to-face contact to monitor the inmate's mental health and identify signs of deterioration. After 30 days in segregation, offenders with serious mental illness should be released unless the warden determines transfer to an alternative housing is not possible. Multiple times per day, correctional officers trained in identifying signs of mental health decompensation should check in with the offender. In addition, at least once per day, medical staff should conduct medical rounds. After 30 days in segregation all offenders should receive a face-to-face psychological review by mental health staff.

Correctional staff training should occur regularly concerning the correctional facilities' segregation policies and support the mind-set that segregation is to be used as the last resort in managing problematic offender behavior. Evaluation of correctional staff compliance with segregation policy should be reflected in yearly employee evaluations. Standing committees, consisting of high-level correctional officials, should be established to ensure regular oversight and evaluation of existing segregation practices. These committees can also develop safe and effective alternatives to segregation.

One of the driving forces behind the aforementioned policy recommendations was the acceptance of the belief that segregation contributes to negative psychological consequences for involved individuals. Meta-analytic research concludes segregation does not produce lasting emotional damage when used for less than 1 year but also does not modify or decrease problematic behavior. The use of segregation may actually increase poor institutional adjustment due to an increase in hostility and aggression. It may also increase recidivism rates. Given this research, it is important to understand what the best practices for programming within segregation units are because segregation will continue to be used in U.S. correctional facilities.

Programming Recommendations

An identified set of best practices for programming in segregation units does not exist. Forensic psychologists, scholars, and correctional officials have, however, started to design, implement, and evaluate programming based on the

evidence-based correctional assessment and treatment principles of risk, need, and responsivity. For example, research indicates educational programming has been related to a decrease in recidivism and institutional misconduct. It has also been positively correlated with postrelease employment. Employment programming is associated with a decrease in prison misconduct and an increase in postrelease employment. Cognitive behavioral therapy has been found to have the best effect on decreasing prison misconduct and recidivism. Social support programming also decreases prison misconduct and recidivism. Interestingly, research indicates reentry programs have improved postrelease employment but less of an impact on prison misconduct and recidivism.

As the research moves forward in identifying effective programming with segregated offenders, correctional officials will need to consider a combination of treatment strategies targeting criminogenic needs associated with a reduction in institutional adjustment and recidivism. The Risk-Need-Responsivity framework provides clear guidance about the approaches most likely to be beneficial in this regard. These include:

- radical behavioral approaches based on the principles of classical and operant conditioning;
- social learning approaches that involve modeling and behavioral rehearsal techniques contributing to self-efficacy; and
- cognitive approaches focused on cognitive skills training, problem-solving therapy, self-control procedures, self-instructional training, and stress inoculation training.

Other promising programming being implemented with segregated offenders includes the application of applied behavior analysis: applying learning theories and behavioral interventions to change specific target behaviors. Promising preliminary results have been reported. Radical behavioral approaches including, at a minimum, tangible, token, and social reinforcers may also be successful. Preliminary results suggest contingency management is an important component of motivating offenders to learn the behavioral skills necessary for positive institutional adjustment.

Small group interventions targeting skills building may also be effective using adapted, structured

treatment curricula focused on emotional regulation. Programming and treatment can be organized into a phase or level system in which inmates can progressively earn privileges and advance through treatment options by demonstrating desired behaviors.

Finally, innovative strategies using telepsychology, such as videoconferencing systems, increase access to of mental health services to segregated offenders. However, early research based on 49 offenders indicated telepsychology was less preferred than in-person therapy sessions. Due to implementation difficulties, before any firm conclusions can be drawn, further research is warranted.

A great deal of support exists for finding alternatives to the use of segregation as a way to manage problematic offender behavior. However, it is likely that some form of segregation will always be a facet of correctional practice to ensure the safety of offenders, institutions, and the public. Therefore, continued work developing a set of best practices for policy and programming with segregated offenders is essential.

SEGREGATION IN PRISONS, DISCIPLINARY

Disciplinary segregation—often referred to as solitary confinement—is a type of restricted housing used in many prisons and jails throughout the United States. The practice of segregation involves the housing of an inmate in conditions characterized by substantial isolation from other inmates. Some claim that disciplinary segregation is a necessary tool for increasing safety and promoting order throughout the correctional system because it deters criminal activity, whereas others insist that the practice actually increases institutional misbehavior, thereby making institutions and the individuals inside them less safe. Many moral, ethical, and legal concerns are raised with the use of this correctional practice. This entry discusses several of the current issues surrounding the contemporary use of disciplinary segregation in the United States.

Disciplinary Segregation

In practice, correctional institutions segregate inmates for several reasons. For example, segregation provides increased supervision and control over inmates who represent a threat to themselves (i.e., *protective custody*) or others (i.e., *administrative segregation*) or who have engaged in serious disciplinary misconduct (i.e., *disciplinary segregation*). Protective custody is used when an inmate needs to be separated from the general inmate population due to personal physical safety concerns (e.g., sex offender, gambling debt, vulnerable inmate). Administrative segregation is used for managerial purposes, including as a response to an inmate who has demonstrated a chronic inability to adjust in the general population or when an inmate’s presence in the general

population is believed likely to seriously disrupt the orderly operation of the institution. Administrative segregation can also be used in some correctional facilities as a temporary housing assignment for inmates pending transfer to another institution, those awaiting a judicial proceeding, when needed to facilitate a criminal investigation, or when limited bed space options necessitate the use of an otherwise empty segregation cell.

In contrast to these other forms of restricted housing, disciplinary segregation is used as a form of punishment for inmates who violate the institution’s rules of conduct. Whenever an institutional violation occurs, a staff member may write up the perpetrator of the incident for the misconduct, and a hearing will be conducted to determine the facts in the case. At the hearing, evidence is presented against the accused, and he or she can either accept the blame (i.e., plead guilty) or defend himself or herself against the charges (e.g., call witnesses on his or her behalf). If the inmate is found guilty by the rule infraction board, a range of sanctions may be imposed upon the offender. These punishments can include the removal of specific privileges, loss of good conduct time, or a sentence for a specific length of time in disciplinary segregation. The type and severity of the specific sanction for any one case is largely contingent upon the nature of the misconduct and the perpetrator’s prior behavioral history in the facility. Departmental regulations often place limits on the amount of time an inmate may be housed in disciplinary segregation depending on the severity of the offense (e.g., 30 days). However, if the inmate has been charged with multiple violations, or if he or she violates the rules while in segregation, the length of stay in disciplinary segregation may be extended.

Conditions in Disciplinary Segregation

The conditions in disciplinary segregation are designed to be unpleasant. These settings provide tight controls over inmates and isolate them from the general population of offenders. The inmates housed in these settings are typically confined to a single cell for up to 23 hours of the day and are only allowed out of their cell for specific purposes, usually for a shower or for exercise. Before leaving their cell for any reason (e.g., medical

appointment, disciplinary hearing), inmates are typically handcuffed and sometimes even shackled at the waist and placed in leg irons. Food is delivered through a slot in the door, meetings with counselors and mental health providers are often conducted through the cell door, and exercise is taken alone in a small, fenced yard area. These inmates are further afforded very few privileges, and they are generally not allowed to participate in any educational, vocational, or other services or programs that are otherwise available to the other inmates living in the general population. Even mental health and medical services are limited for prisoners in segregation. Family visits in disciplinary segregation are often prohibited, and in the rare event that a family visit is allowed, the interactions are usually noncontact and are conducted via a telephone with a thick glass window separating the inmate from his or her family member.

Prevalence of Disciplinary Segregation

Many jails and prisons do not track their use of disciplinary segregation or do so in an accessible way, so it is difficult to determine the prevalence of disciplinary segregation in the United States. Estimates of the number of offenders in restricted housing have ranged from 20,000 to 100,000. Furthermore, the extent of the use of segregation also appears to vary widely among states—for example, a 1998 survey of State Department of Corrections reported percentages of inmates in such settings as ranging from less than 1% (e.g., Pennsylvania) to 12% (e.g., Mississippi). Another challenge for determining the extent of the use of disciplinary segregation is that inmates are often subjected to the setting for relatively short durations (e.g., <30 days). This means that any estimate derived from taking a snapshot of the inmates in segregation at only one point in time is likely to underreport the true number who have experienced disciplinary segregation because there may be many inmates who occupy a specific segregation cell over a given length of time.

In 2011 and 2012, researchers from the U.S. Bureau of Justice Statistics conducted a study that surveyed a national representative sample of prisoners incarcerated across the United States. This study found that approximately 18% of jail and prison inmates surveyed spent time in a restricted

confinement setting in the previous year. This estimate includes inmates in segregation for both disciplinary and administrative reasons, so it is still largely unknown how widely disciplinary segregation is specifically used in the United States.

The Effects of Disciplinary Segregation

There is a widely held belief among policy makers and corrections officials that the use of disciplinary segregation increases safety, order, and control in prisons. In contrast, those critical of the practice maintain that the segregation setting itself is responsible for causing serious psychological and other health problems as well as increases criminogenic risk. Despite its long history of use and recent increase in public attention, segregation more broadly, and disciplinary segregation specifically, has remained an elusive subject of empirical research.

A review of the segregation literature reveals that there are several limitations to understanding what effect disciplinary segregation may have on inmate outcomes. For example, the majority of the research in this area has been qualitative in nature rather than empirical. That is not to say that impressive empirical evaluations do not exist, but rather that they are the exception and not the rule. Therefore, most of what is known about the effects of this practice on inmate outcomes is based on subjective evidence. Qualitative researchers in this area have primarily used information from interviews with inmates and other mental health professionals working in segregation settings to show that the practice violates prisoners' constitutional rights, contributes to psychological problems, increases criminogenic risk, and is used excessively in the United States. These anecdotal studies have often been found in the popular press and other media outlets and tend to promote the idea that segregation has serious detrimental effects on inmates. It has been these perceived negative effects that have helped make this practice an issue of national attention.

Other scholars, however, have pointed out several methodological limitations on which much of this literature is based (e.g., selection bias, response bias, inadequate or no control groups). These scholars caution that researchers and practitioners should be cautious in drawing firm conclusions

from this group of works. Two meta-analytic reviews on this topic have found that the magnitude of the effects from the available empirical studies tends to be much smaller than that has been predicted by those critical of the practice.

The majority of the research in this area has further been limited to examining the effects on inmates residing in administrative segregation settings—and in particular those in supermax facilities—rather than on those who are held in segregation for disciplinary reasons. What is more, most of the research that has examined the behavioral effects of segregation has been limited to postrelease (e.g., recidivism) rather than institutional outcomes (e.g., institutional misconduct). There are now a handful of empirical studies that indicate that the experience of segregation may increase offender postrelease recidivism. One study in particular found that these effects were much worse for those inmates who were released directly into the community from the segregation setting compared with those who were stepped down from segregation into the general prison population before being released.

The available empirical research in this area has also been plagued by some serious limitations. For example, it has often been difficult for evaluators to acquire comparable control groups for those inmates housed in segregation (e.g., the modal response to violent behavior in prison is to place inmates in segregation). Therefore, if researchers are not careful in their selection of an appropriate control group, they may attribute a cause of placement in segregation for its effect. It is worth noting that for the studies that are of higher methodological quality (i.e., those that are able to match on a wide variety of other known predictors of criminal behavior), the magnitude of the effect sizes has been much smaller and in some studies has been reported as zero, whereas those studies with less rigorous research designs (i.e., do not control for other predictors of criminal behavior) have tended to yield much larger effects. Nonetheless, there is a tentative support for the contention that segregation may increase offender postrelease recidivism; however, much less is known about how this practice influences inmate adjustment in prison. In 2015, two studies found that short-term disciplinary segregation had a null effect on measures of subsequent institutional misconduct. However,

there is clearly a need for more empirical research on the effect of disciplinary segregation on subsequent institutional behaviors.

The Future of Disciplinary Segregation

The primary purpose reported for the use of disciplinary segregation is that the practice is necessary to ensure reductions in violence and other serious disruptions within the prison system. The use of segregation as a response to inmate misbehavior may be appealing to some correctional authorities because of its simplicity; however, there is little evidence available that supports these settings as an effective strategy for reducing inmate misconduct and postrelease recidivism. Furthermore, disciplinary segregation is only theoretically capable of influencing inmate behavior, as a specific deterrent, after an initial infraction has been committed. Many argue that if disciplinary segregation does not improve inmate behavior, and it costs considerably more than standard housing, it is perhaps time for policy makers to seriously consider other alternative strategies for dealing with such rule violators. There are several attempts currently underway across the country to develop safe alternatives to segregation that will both ensure institutional safety and improve inmate outcomes.

SELF-APPRAISAL QUESTIONNAIRE (SAQ)

The Self-Appraisal Questionnaire (SAQ) is a theoretically and empirically based instrument. It is the first multidimensional self-administered questionnaire that was specifically designed to predict violent and nonviolent offender recidivism among correctional and forensic populations and to assist with the assignment of these populations to appropriate treatment or correctional programs and different institutional security levels. It was designed to be multifaceted, covering content areas that have been demonstrated to be important for measuring criminogenic factors related to the assessment of recidivism and treatment of offenders. After further describing the SAQ, this entry discusses its uses, describes how to score and interpret, and reviews its reliability, validity, and advantages.

Description of the SAQ

The SAQ was developed in 1996 and published in 2005 with the Mental Health Systems, Toronto. It was designed to cover the predominant predictive areas found in the offender recidivism literature, as some of these areas were ignored or not adequately covered by other tools. The SAQ consists of 72 items, with seven subscales that measure quantitative criminogenic risk/need areas. The first subscale, Criminal Tendencies, taps antisocial attitudes, beliefs, behaviors, and feelings. These tendencies are considered central to the major theories of criminality and the prediction of recidivism. Previous studies, including meta-analysis studies, indicated that the best

individual predictors of recidivism were attitudes, values, and behaviors that support a criminal lifestyle.

The second SAQ subscale is Antisocial Personality Problems. This subscale covers characteristics similar to those used to diagnose antisocial personality disorder, which has been the psychiatric diagnosis traditionally used to predict recidivism. Self-reported antisocial personality characteristics have been shown to predict static and dynamic factors of violent recidivism.

The third subscale, Conduct Problems, assesses childhood behavioral problems. Research has indicated that conduct problems during childhood are among the best predictors of later offending and the development of a criminal career. The fourth subscale considers the offender's Criminal History, as past criminality has been shown to be a robust predictor of future criminal acts.

The fifth subscale is Alcohol/Drug Abuse. The relationship between substance abuse and crime, including violence, is well documented and has been found to correlate with recidivism. The sixth subscale assesses Anti-Social Associates, an area with demonstrated value in the prediction of recidivism.

The seventh subscale, Anger, measures the offender's reaction to anger. This scale is not included in the total score of the SAQ due to the controversial and unconfirmed relationship between anger and recidivism. This subscale could be useful in assigning offenders to anger management or control programs. The Validity scale is a subscale that can be used to validate the offender's truthfulness in responding to the SAQ's items.

Uses of the SAQ

The SAQ can be used for several purposes. First, the SAQ can be used to predict postrelease adjustment such as violent and nonviolent recidivism, parole violations, and probability of being convicted of a new offence. The SAQ can also be used to assign offenders to institutional security levels and predict institutional adjustment. Another purpose of the SAQ is the assignment of offenders to treatment programs such as substance abuse, anger management, cognitive skills, and programs dealing with antisocial attitudes, antisocial behavior,

antisocial feelings, antisocial beliefs, insight, and similar types of programs. In addition, the SAQ provides information that may assist with diagnosing a substance abuse problem, conduct problems, and antisocial personality disorder. Finally, the SAQ can be used as a pretreatment and posttreatment measure to assess the effect of treatment and determine changes in offenders' attitude and attributions, particularly those related to the offender's criminal tendencies.

Uses of the SAQ by Correctional and Forensic Professionals

The SAQ can be used by professionals and non-professionals alike due to its ease of use. Psychiatrists and psychologists may use the SAQ to reach diagnoses related to antisocial personality disorder, conduct disorder, and substance abuse. They may also use the SAQ to make predictions regarding the level of risk a particular offender may pose upon release from prison as well as predictions regarding institutional adjustment. Furthermore, psychiatrists and psychologists may use the SAQ for program participation suggestions, to design individualized treatment plans to deal with offenders' inappropriate responses to the SAQ's items, and to follow up treatment gains. Case managers may use the SAQ to help them make decisions regarding the level of risk a particular offender may pose if released, to determine program needs, and to make appropriate referrals. Program delivery officers may use the SAQ to assign offenders to appropriate programs according to their needs; for example, offenders with high scores on the SAQ Criminal Tendencies subscale could be offered a cognitive behavior program. Similarly, offenders with high scores on the SAQ Alcohol/Drug Abuse subscale could be offered participation in substance abuse programs. Likewise, offenders with high scores on the SAQ Anger subscale may be offered an anger management program. Parole officers/case managers, program officers, and counselors can design individualized treatment plans to deal with offenders' inappropriate responses to the SAQ's items. Staff, regardless of their professional background, can use the SAQ as a pre- and a postmeasure to assess changes in offenders' attitudes and beliefs. Lastly, researchers can include the SAQ in research projects.

Instructions for Completing the SAQ

After explaining the purpose of the questionnaire, the person administering the SAQ simply asks the offender to read the instructions for completing the SAQ aloud. Essentially, the offender is asked to answer with a true or false response to the included statements. The person administering the SAQ may respond to an offender's request for clarification in a manner that does not influence the offender's response. After the offender completes the SAQ, the person administering the SAQ checks for unanswered questions, as ideally, no item should be left unanswered. Occasionally, an offender may not be able to easily answer a question, so the person administering the SAQ can explain the question to the offender and obtain a response. If more than 3 items are left unanswered, the results of the particular scale that those items contribute to may be affected but not necessarily the result of the whole test.

Offenders who can read and comprehend what they read can complete the SAQ. If a client does not have the requisite literacy skills (e.g., fifth-grade reading level), the person administering the SAQ can read the items to the client without interpretation and entered the client's responses on the answer sheet.

Scoring the SAQ

Scoring the SAQ typically takes just a few minutes. The total SAQ score is the aggregate of the SAQ subscale scores. Completing the Validity scale of the SAQ involves verifying the accuracy of the offender's responses on some items through his or her criminal history.

Interpreting and Reporting the Results of the SAQ

The offender's level of risk/needs is reported, according to the established norms, the in either Low, Low-Moderate, High-Moderate, or High range of committing a violent and nonviolent offense within a period of approximately 2 years after the offender's release from prison. Results could also be reported in percentiles. Some clinicians prefer to include the offender's scores on the subscales, especially if the scores are elevated.

Instructions on the SAQ answer sheet provide direction about the level of risk/needs and possible management consideration. For example, a score of 43 or more indicates a high probability for violent and nonviolent recidivism and indicates a need to assign the offender to a maximum-security institution. An offender with a score from 23 to 42 is considered at a moderate-to-high risk of violent and nonviolent recidivism and may be considered for medium-security institutions. Suggestions for program assignments based on SAQ subscale scores are also included in the instruction sheet. An offender with a score from 11 to 22 is considered at a low-to-moderate risk of violent and nonviolent recidivism, and assignment to a minimum- or medium-security institution should be considered. An offender with a score of fewer than 11 is considered at a low risk of violent and nonviolent recidivism and could be considered for assignment to a minimum-security institution. He or she may not need to participate in programs.

User Qualifications

The SAQ can be administered and scored by clerical staff after a short training session; however, interpretation should be done by a psychologist, behavior specialist, case manager, social worker, or other staff member who is experienced in the assessment of human behavior in a correctional or forensic setting. Minimal training is required for correctional and forensic professionals to be able to administer and interpret the SAQ.

Reliability and Validity of the SAQ

Numerous studies have demonstrated the concurrent, construct, and predictive validities of the SAQ. The follow-up predictive studies demonstrated the predictive validity of the SAQ over 2-, 5-, and 9-year periods on Canadian offenders. The SAQ has also been validated on samples from the United States, Australia, Canada, Great Britain, Singapore, Spain, South Africa, and several European countries. Samples included Caucasians, African Americans, Asians, Aboriginals, Hispanics, and offenders from other origins. The SAQ has also been validated on women, youth, and offenders with mental illness. Comparative predictive studies—which included other measures—over 2- and 5-year periods have demonstrated that

the SAQ is at least as effective as well-recognized clinician-administered measures. A meta-analysis study that included 10 measures indicated that the SAQ was more predictive of violent reoffending than eight other well-known predictive measures. In addition, two studies have demonstrated that the SAQ as a self-report is not affected by self-biases, lying, and/or deception. The results of these two studies and the result of the meta-analysis refute the claim that self-report measures are not as effective as professionally administered measures.

Advantages of the SAQ

There are practical advantages of using the SAQ in addition to its coverage of the predominant content areas supported by the prediction literature. The SAQ is a self-report questionnaire, and there is evidence that self-report questionnaires can be equivalent to traditional methods of predicting violent recidivism and nonviolent recidivism. Self-report ensures maximal objectivity by avoiding possible misinterpretation of offenders' responses and reducing the possibility of assessor biases. It also decreases the possibility of litigation due to the offender's perception of misrepresentation by engaging the offender in the assessment process. In addition, the SAQ is more convenient and economical to use than traditional methods of risk assessment. Instructions are provided and can be given by paraprofessionals. It usually takes approximately 15–20 minutes to complete, with offenders providing *yes* or *no* responses to the items. The SAQ may also be administered in a group session. Interpreting the results requires minimal professional time and training, so prior extensive experience and/or special skills are not needed to credibly and reliably interpret its results.

Furthermore, the SAQ incorporates a large number of dynamic risk factors, in contrast to some other well-established risk tools that do not include any dynamic factors. In addition, when applying the SAQ, one may subsequently use many of the offender's responses as part of an individualized cognitive treatment plan. For example, irrational or faulty cognition demonstrated through the endorsement of statements such as "I can fool most people if I want" or "Almost anyone would lie to save himself from trouble" can be challenged during treatment. Moreover, the endorsement of some of

the SAQ's statements could aid clinicians in the diagnosis of antisocial personality disorder and a history of conduct disorder and substance abuse. A focus on content areas particularly related to the prediction of violent recidivism during the development of the SAQ is also an advantage, as is its lack of reliance on the results of other tools or sources. A final advantage of the SAQ is that neither its items nor its total score may be used to attach negative labels to the offenders.

In spite of the several studies that demonstrated the reliability and validity of the SAQ, a 2006 study by Ojmarrh Mitchell and Doris Layton MacKenzie questioned the predictive validity of the SAQ. However, in 2007, Gurmeet K. Dhaliwal, Wagdy Loza, and John R. Reddon demonstrated their erroneous conclusion.

SELF-REGULATION

Self-regulation refers to the monitoring of one's own behavior through the lens of prevailing moral and social conventions and the subsequent modification of behavior that is discrepant with personal goals and/or standards. Criminal behavior is inherently tied to the construct of self-regulation. Behaviors such as sexual offending, violence, and general antisociality are associated with a failure to modify behavior according to societal standards. Within the criminal justice system, there is a significant heterogeneity with respect to crimes committed and characteristics of criminal offenders. Accordingly, there are numerous factors that undermine self-regulatory capacity and thus contribute to criminal behavior. This entry focuses on mechanisms underlying self-regulatory failure that contributes to criminality, explains how these mechanisms are linked to distinct criminal types, and then explores the implications for treatment and prevention.

Processes Involved in Self-Regulation

In general, self-regulation relies on a feedback loop involving the establishment of a desired state, assessment of the current state, comparison of the two states, and behavioral reform to reduce the identified discrepancy between the two states. For instance, an inmate recently released on parole may have the goal of following parole requirements, such as not using controlled substances and not associating with criminal influences, to avoid reincarceration. Fundamentally, self-regulation depends on the ability to focus selectively on relevant stimuli and ignore nonrelevant stimuli. Self-regulation can be conceptualized as the context-appropriate allocation of attentional resources to dominant (i.e., related to an individual's dominant response set) and nondominant information. A dominant response set is a prepotent or well-learned response. Dominance is defined in terms of neural network activation, with the most dominant response relating to the most active network. In the case of the parolee, dominant responses relate to overlearned behaviors (e.g., doing drugs or associating with other felons), while

nondominant responses relate to other, less automatic behaviors (e.g., seeking out the company of a nondelinquent peer or looking for employment opportunities). When a dominant response is adaptive for a given context, self-regulation is unnecessary since the dominant network determines the behavior. However, when the most adaptive response is nondominant, selective attention is necessary to activate this network. For instance, selective attention would be required to shift attention from drug cues to parole conditions. Dysregulation often reflects a failure of selective attention to activate more adaptive, nondominant neural networks or failure to keep a relevant network activated while suppressing irrelevant ones.

Pathways to Undersocialized Behavior

Multiple pathways contribute to self-regulatory failure. First, attention may be overallocated to dominant cues, precluding the accommodation of nondominant information. Second, maladaptive emotional cues might hijack attention. Third, deviant developmental influence may encourage misregulated (or wrongly regulated) behavior. Lastly, intellectual deficits can impede the ability to control one's thoughts, behaviors, and feelings to reach goals.

Failure to Integrate Bottom-Up Input

Attentional dysfunction can undermine self-regulation by restricting the processing of contextual information that guides adaptive behavior. Difficulty automatically shifting attention to accommodate nondominant or set-incongruent information would undermine the ability to register contextual information or response conflict. As a result, peripheral information needed to inform self-regulation would not be integrated with ongoing goal-directed behavior. Failure to integrate nondominant information may relate to difficulty simultaneously processing multiple streams of information or to the overallocation of top-down resources to dominant cues. For instance, a salesman may focus on reaching a sales goal and overlook the long-term implications of selling a product below cost: bankruptcy and the ultimate termination of his job. Alternatively, a corporate

official may overlook the detrimental impact of an embezzlement scheme on her or his employees' livelihoods due to her or his focus on her or his own monetary gain.

Emotion-Based Overfocusing

An alternative mechanism underlying dysregulation involves the overallocation of attention to maladaptive, affectively laden cues. Differences in attentional allocation to affective stimuli relate to differences in temperamental reactivity. Neuroticism is a personality trait characterized by emotional lability and proneness to negative affect. It is associated with attentional biases toward certain types of information. Individuals high in neuroticism and extraversion typically overallocate attentional resources to rewards cues, while *neurotic introverts* preferentially allocate attention to punishment cues. The presence of salient information can hijack attentional resources necessary for adaptive inhibition, thereby disrupting the balance of attention toward dominant and nondominant cues and causing dysregulation. Examples include a recently sober drug addict who relapses after walking past a former hangout or an individual initiating a physical fight following a perceived insult.

Inadequate Socialization

Inadequate socialization is a third pathway to dysregulation. Socialization is the process by which individuals learn social norms and values to help them function in their environments. Environments characterized by violence or parental malfeasance (e.g., abuse, addiction, crime) may reinforce deviant acts, as these behaviors enable an individual to cope with and succeed in the environment. For example, an adolescent might be exposed to new opportunities to participate in criminal activities following indoctrination to a local gang, which he sought in the absence of parental involvement.

Cognitive Deficits Hampering Socialization

A final pathway to dysregulated behavior involves cognitive deficits that undermine interpersonal functioning and impulse control. Low verbal intelligence (i.e., poor verbal

comprehension) can interfere with social skills learning and the development of positive interpersonal relationships, placing an individual at a heightened risk of conflict with social rules and low peer acceptance. Executive functioning deficits are associated with emotional immaturity, poor decision-making skills, and reduced capacity for effortful self-control. Low self-control is, in turn, associated with difficulty deferring gratification and increased risk of impulsive aggression. These factors, in combination with adverse early environments, can increase the risk of delinquent behavior among juveniles. For instance, an adolescent with low self-control might have insufficient ability to resist stealing a desired article of clothing when the opportunity arises and then might lack sufficient insight to see the connection between her or his behavior and its consequences.

Self-Regulation and Criminal Types

The criminal justice system historically recognizes four criminal typologies resulting from psychopathological disorders in childhood: unsocialized–psychopathic, disturbed–neurotic, subcultural–socialized, and inadequate–immature. Each of these criminal types reflects a different pathway to undersocialized behavior.

Psychopathy

Psychopathy is a clinical construct characterized by diverse interpersonal, affective, and behavioral symptoms, including shallow affect, grandiosity, impulsivity, and antisociality. Undermining psychopathic offenders' self-regulatory abilities is their difficulty automatically shifting attention to and integrating nondominant cues during goal-directed behavior. Failure to fully process secondary information or multicomponent stimuli precludes constraining influences on ongoing behavior. In the case of psychopathy, this is perhaps the most salient in situations necessitating the processing of secondary affective or inhibitory cues (e.g., victim distress or the presence of law enforcement). Psychopathic offenders are also less likely to experience self-conscious emotions (i.e., guilt and empathy) since the experience of these emotions relies on shifting attention toward the self.

Externalizing

The externalizing construct pertains to a latent etiological factor underlying antisocial personality disorder, conduct disorder, and substance abuse and dependence. The core features of externalizing disorders overlap significantly with psychopathy, although the processes underlying these conditions are distinct. Externalizing is characterized by high levels of neuroticism and extraversion, which predispose individuals to preferentially overallocate attention to affectively valenced information. The preferential recruitment of attention for processing motivationally significant information undermines effective effortful control (i.e., cognitive control). Effortful control enables the inhibition of prepotent impulses to permit the performance of subdominant responses. Externalizers demonstrate poor effortful control when confronted with reward cues, frustration, and interpersonal slights and have difficulty overriding maladaptive, impulsive behavior to act in an adaptive manner.

Sociopathy

Although sociopathy is largely indistinguishable from psychopathy (i.e., both are characterized by callousness, impulsivity, and criminal tendencies), the mechanisms underlying the conditions differ. Whereas psychopathy involves a fundamental deficit in attentional processes, sociopathy stems from maladaptive social learning. Early exposure to disorganized environments characterized by violence or neglect can produce long-lasting changes in affective and neuroendocrine responsiveness to stress and can increase aggressive behavior. Additionally, factors such as inconsistent or hostile parenting can undermine the process of socialization, cultivating a disregard for social norms. Social influences can also contribute to the disengagement of internal regulatory mechanisms that restrain violence. This process is often seen in radical terrorist groups. Predisposing developmental factors influence individuals to join terrorist groups, while dogma surrounding the justifiability of violence and the minimization of harm, combined with anger, alienation, disenfranchisement, and group kinship, can encourage the misregulated behavior.

Inadequate/Immature Delinquency

Offenders within the inadequate/immature typology typically demonstrate poor social skills, learning problems, and deficient impulse control. They are typically easily overwhelmed and lack mature judgment. As noted, individuals with various neuropsychological deficits are at a heightened risk of socialization difficulty, particularly in the context of criminogenic environmental influences. Reduced cognitive capacity may prevent inadequate/immature offenders from learning effective emotion regulation or social skills and from understanding the legal ramifications of engaging in delinquent behavior. These individuals have difficulty resisting temptations afforded by environmental circumstances and the leadership of a more mature peer.

Implications for Prevention and Treatment

The heterogeneity of mechanisms underlying self-regulatory dysfunction has important treatment implications. Specifically, it suggests that there is no panacea for dysregulation and criminality. Regardless of the cause, early intervention is likely to optimize outcome effectiveness.

Cognitive Remediation

Cognitive remediation is an intervention designed to improve various cognitive abilities, including attention and components of executive functioning. As noted, psychopathy is characterized by attentional difficulties resulting in a failure to integrate contextual or multicomponent information necessary for effective regulation of goal-directed action. There is evidence demonstrating generalized improvements in attention to context following cognitive remediation therapy for psychopathic offenders. Psychopathic individuals show increased responsiveness to information outside their attentional focus following laboratory-based training balancing attention between primary and secondary information. There is further evidence that training children with callous-unemotional (i.e., psychopathic) traits to attend to and identify facial emotion improves empathic responding.

Affective Cognitive Control

Early interventions show promising results in decreasing disinhibition that typifies externalizing psychopathology. Treatment programs that focus on improving emotion regulation skills and on teaching caregivers effective parenting skills relating to communication, discipline, and boundary-setting are associated with significant decreases in aggressive behaviors and improvements in emotion identification and management. Treatment approaches aimed at the development of emotion regulation skills also demonstrate efficacy in adult offenders with externalizing problems. Specifically, externalizing offenders show decreased hyperreactivity to affectively charged circumstances following training in affective cognitive control.

Social Interventions

Prevention efforts for sociopathy should target environmental factors that perpetuate delinquency. From a socioecological perspective, crime stems from the interaction of individual vulnerabilities, interpersonal relationships, and societal variables. Accordingly, treatments that overlook adverse social influences to focus on individual factors will ultimately fail. Effective interventions for decreasing dysregulation include reducing social isolation and increasing positive peer involvement, cultivating economic opportunities in neighborhoods, and developing prosocial programs and policies within school and workplace settings.

Verbal and Social Skills Training

Interventions focusing on improving language-based verbal skills (i.e., comprehension and communication) and diffusing emerging conflicts by nonphysical means significantly reduce dysregulated behavior among individuals with the specified neuropsychological deficits. If an intervention occurs at an early age, it may help at-risk youth or behavior-disordered children with low verbal intelligence overcome the language deficit that contributes to maladaptive social behavior. Individuals with limited self-awareness and poor decision-making skills may benefit from compensatory cognitive training in areas such as

prospective memory, attention, learning, problem-solving, and cognitive flexibility.

SELF-REPORT MEASURES OF PSYCHOPATHY

The use of self-report measures to assess psychopathic personality or psychopathy (i.e., a constellation of personality traits and behaviors encompassing guiltlessness, superficial charm, grandiosity, callousness, poor impulse control, and manipulateness) has been fraught with controversy. Until approximately the 1990s, the overwhelming majority of psychopathy research was conducted in forensic and clinical settings. Since the 1990s, however, interest in studying psychopathic traits in nonclinical settings, such as college and community samples, has burgeoned. Moreover, accumulating research evidence suggests that psychopathy differs in degree rather than kind from normality and is probably underpinned by one or more subdimensions. Given these findings, some researchers have argued that psychopathy can be studied profitably among noncriminal populations by means of self-report measures. Self-report measures have become the predominant mode of psychopathy assessment among nonclinical participants, such as those in college

and community samples. This entry addresses the potential disadvantages and advantages of self-report psychopathy measures.

Criticisms and Potential Disadvantages

Self-report psychopathy measures have been met with some criticism. Critics of self-report psychopathy measures point to a variety of features associated with psychopathy, including dishonesty, manipulateness, grandiose sense of self, and lack of insight, which preclude individuals' ability to report accurately on their attributes. These criticisms typically reflect skepticism that individuals with extreme psychopathic features are either unwilling or unable to present themselves accurately. This notion is held widely in clinical psychology and psychiatry circles, even among psychopathy researchers.

Dishonesty

The most obvious characteristics of psychopathy believed to adversely affect the validity of self-reports are dishonesty and manipulateness. Psychiatrist Hervey Cleckley, who introduced the psychopathy construct to the clinical community in 1941, noted astutely that “the psychopath shows a remarkable disregard for truth.” The lion's share of research investigating this concern has focused on psychopathy's relations with response bias, reflecting either a conscious or an unconscious motivation to present oneself inaccurately. Nevertheless, when examined meta-analytically, psychopathy does not relate markedly to various indices of response bias, such as social desirability. In fact, psychopathy is typically negatively associated with underreporting of negative features (i.e., *faking good*) and positively associated with overreporting of negative features (i.e., *faking bad*). Contrary to clinical lore, psychopathic individuals are willing to admit to many socially undesirable characteristics and are consistent with higher levels of negative emotionality found in those with chronic antisocial behaviors and impulsivity, which are commonly associated with psychopathy.

Lack of Insight

A second characteristic of psychopathic individuals thought to adversely affect their self-reports is lack of insight. Cleckley conjectured that

psychopathic individuals lack the capacity to see themselves as others see them, calling into question their ability to introspect accurately. Nevertheless, scant research has examined *blind spots* in psychopathic individuals' self-perception. It is well established that psychopathic individuals are higher in blame externalization, a trait that is assessed explicitly in certain self-report psychopathy measures. Although there are several potential explanations for this finding, the presence of elevated levels of this trait leaves open the possibility that psychopathic individuals possess little insight into their problematic behavior.

Self-Report Versus Informant Report

Another line of research has explored the convergence of self-reports and informant reports of psychopathic traits. The findings in this domain are somewhat mixed, but most studies demonstrate that self-reports and informant reports of psychopathy demonstrate modest to high overlap. These findings suggest that psychopathic individuals are not entirely devoid of the capacity to report accurately on their traits and behaviors. Moreover, there is only modest support for the notion that psychopathic individuals rate themselves as less psychopathic than their peers rate them. Nevertheless, the lack of complete overlap between the two types of reports leaves open the possibility that lack of insight attenuates the validity of self-reports among psychopathic individuals. It is also possible that self-reports are equally as valid as other forms of psychopathy measures. Along these lines, self-reports need not be factually accurate to yield diagnostically useful information. For example, a psychopathic participant may respond *True* to the item "I've never done anything I ought to feel guilty about" even though such a response is almost surely factually inaccurate. Indeed, the lack of overlap between reports may implicate a lack of insight and reflect a distorted, yet sincere self-perception.

Potential Advantages

Psychologist Gordon Allport argued that the self is in a privileged position and that if psychologists want to understand people's personalities, they should just ask them. Consistent with this position, self-report psychopathy measures possess

important potential advantages over other types of measures. First, self-reports are economical, and they are often more efficient in terms of cost and ease of administration compared with interview-based measures. Second, self-reports circumvent the problems posed by interrater reliability and subjective clinical inference. Third, an often-overlooked advantage of self-reports relative to interview-based measures is that they allow for the systematic assessment of response biases, which can be measured using built-in validity scales designed to detect lying, social desirability, and malingering, all of which may be more prevalent among psychopathic individuals than among nonpsychopathic individuals.

Final Thoughts

The debate over the validity of self-report psychopathy measures remains contentious. On balance, despite skepticism and criticisms, self-reports have been shown to be reliable and reasonably valid indicators of psychopathic personality features. Perhaps for this reason, self-reports are becoming the most widely used instruments for assessing psychopathy in nonforensic, nonclinical populations. Nevertheless, future research is needed to explore the validity of self-reported personality measures and the extent to which these tools compare with, and perhaps add to, interview-based measures in the prediction of important life outcomes (e.g., criminal behavior and interpersonal deception).

SELF-REPORT PSYCHOPATHY (SRP)

The SRP scale was designed by Robert D. Hare as a self-report version of his Psychopathy Checklist (PCL) and its revision (PCL-R). Originally created using correctional and forensic populations, the PCL-R is a 20-item construct rating scale that conceptualizes psychopathy as a superordinate dimensional construct composed of four correlated factors: *interpersonal* (glibness/superficial charm, grandiose sense of self-worth, pathological lying, conning/manipulative), *affective* (lack of remorse or guilt, shallow affect, callous/lack of empathy, failure to accept responsibility for actions), *lifestyle* (need for stimulation/proneness to boredom, parasitic lifestyle, lack of realistic long-term goals, impulsivity, irresponsibility), and *antisocial* (poor behavioral controls, early behavior problems, juvenile delinquency, revocation of conditional release, criminal versatility). Based on a structured interview and file review, PCL-R items are scored on a 0–2 ordinal scale with a recommended *diagnostic* cutoff score of 30 or above for research and forensic purposes.

The PCL-R is considered the international standard for the assessment of psychopathy and helped to significantly advance understanding of the construct by providing a common metric for researchers and clinicians. However, as with any psychiatric interview, the PCL-R requires extensive training and skilled clinicians or researchers to administer it. Thus, the time and cost to train and administer the PCL-R, along with the low prevalence of clinically diagnostic psychopathy in the general population (approximately 1%), lead it to be less practical for nonforensic settings. In addition, certain PCL-R

items that are relevant in offender settings (e.g., revocation of conditional release, criminal versatility) may not be appropriate for community samples. For research in the general population, Hare and colleagues developed the SRP. This entry focuses on the development and utility of the SRP, as well as its strengths and critique of other psychopathy self-report measures.

SRP Development

Hare developed the initial versions of both the SRP and the PCL in 1985 after finding that early measures used to assess psychopathy (e.g., Psychopathic Deviate scale from the Minnesota Multiphasic Personality Inventory and the Socialization scale from the California Psychological Inventory) had weak associations with each other and the early PCL. The SRP was developed using standard item reduction procedures to identify items related to psychopathy. Despite developing the initial SRP in the same theoretical framework as the PCL, the agreement between the two instruments was modest. To refine the SRP, Hare and colleagues developed the SRP-II in 1991 to reflect the two-factor structure of the PCL-R. Factor 1 of the PCL-R includes the interpersonal and affective components of psychopathy, and Factor 2 combines lifestyle and antisocial factors. To reflect the PCL-R changes, the SRP-II was expanded to a comprehensive 60-item measure with 31 items specifically designed to capture the two-factor structure. The validity of the SRP-II was bolstered by robust positive correlations with the PCL-R in both clinical and forensic samples. In nonforensic settings, Delroy Paulhus and his colleagues found that SRP-II total scores correlated positively with a variety of antisocial behavioral (e.g., delinquency) and personality (e.g., disagreeableness, promiscuous sexual attitudes) variables.

Despite these positive findings, Paulhus and his colleagues found limitations in the SRP-II. One limitation was that the factor structure did not mirror that of the PCL-R. Instead, the first factor was a combination of antisocial behavior, impulsivity, and interpersonal manipulation, which Paulhus termed *impulsive trouble-making*; the second factor, emotional stability, contained items pertaining to low anxiety and high self-confidence. The latter factor corresponded to low

scores on the neuroticism factor of the Five Factor Model of personality.

To address these limitations, Paulhus, Hare, and colleagues refined the SRP-II. They suggested that the inclusion of anxiety-related items and the absence of items related to antisocial behavior were major reasons for the discrepant factor structure. It became evident that (low) anxiety was not an essential feature of SRP psychopathy. Similarly, research with other SRP measures with anxiety-related items (e.g., the Minnesota Temperament Inventory) found that they did not covary meaningfully with core psychopathy traits, thus warranting their removal. In addition, meta-analytic research has shown that low constraint and poor threat detection are more fundamental to psychopathy than low anxiety. Another limitation of the SRP-II was that it did not reflect the four-factor model of psychopathy, initially proposed in the second edition of the PCL-R in 2003. As Hare and Craig Neumann have documented, there is extensive evidence for the four-factor model based on behavioral, genetic, longitudinal, and latent variable modeling research.

To address these issues, Paulhus and colleagues removed items related to anxiety and added several items tapping into the four dimensions of psychopathy, which resulted in a 77-item experimental measure referred to as the SRP-E. Research with the SRP-E found a correlated four-factor structure: with factors labeled interpersonal manipulation, criminal tendencies, erratic lifestyle, and callous affect. This four-factor model mirrored the four-factor model of the PCL-R as well as scales developed in the same theoretical network such as the screening and youth versions of the PCL-R. Further refinement of the SRP-E led to the development of the modern 64-item SRP-III, which can also be reliably administered as a short 29-item form called the SRP-SF, developed via model-based measurement theory. Despite some minor differences, the SRP-III and the SRP-SF are strongly intercorrelated (e.g., $r = .92$), show significant overlap in predicting relevant variables related to psychopathy, and both replicate the PCL-based four-factor latent variable model of psychopathy.

Drawing on the SRP-III and SRP-SF research, the SRP-4 was published in 2016. The SRP-4 comes with an in-depth manual that provides

norms based on large community, college, and offender samples; scoring procedures; and a comprehensive body of construct validation evidence for both the full and short form versions. Although the total scores on all versions of the SRP yield virtually identical results, only the SRP-4 and SRP-III have the four-factor structure that permits scoring of all four subscales commensurate with the PCL-R.

Strengths

The modern SRP, a self-report analogue of the PCL-R, has several notable attributes. A major strength is the mathematically strong and theoretically sound latent structure of the measure. On a practical level, this means that responses to the SRP items are highly discriminating of persons who are low versus elevated on psychopathic propensities. In addition, the four-factor structure is invariant across gender and provides a model that can capture psychopathic features across diverse samples (i.e., student, community, offender). Moreover, based on a mega-world sample of 33,016 individuals, the four-factor structure of the SRP showed excellent fit, suggesting that it can be used to assess psychopathic personality across the globe. Furthermore, the SRP has demonstrated strong relationships with the Youth Psychopathic Traits Inventory, measures of *dark* personality traits, and a psychopathy self-report based on the Five Factor Model of personality (Elemental Psychopathy Assessment), indicating that there is a sound theoretical framework surrounding the SRP and this set of measures.

Additional construct validity comes from the fact that elevated SRP scores are associated with relevant external correlates. Specifically, the SRP has been found to be predictive of violence and serious offending behavior, above and beyond other indicators of offending risk. In addition, elevated SRP scores are associated with less empathetic concern and amoral reasoning. Furthermore, the SRP is significantly linked with reduced amygdala activation and volume, an area of the brain associated with emotional processing, in concordance with previous neuroimaging psychopathy research on forensic samples. In the general population, researchers have also found that elevated SRP scores are associated with

behavioral indicators of scholastic cheating, fraud, bullying, and drug use. These findings illustrate that SRP traits predict critical external variables associated with psychopathy.

Critique of Other Popular Self-Report Measures of Psychopathy

Since the development of the first SRP, several self-report scales putatively measuring psychopathy have emerged, though questions have been raised regarding their theoretical basis and the items used in the scales. In contrast to the concordance between the SRP, the PCL scales, and other psychopathy assessments (e.g., Elemental Psychopathy Assessment, Youth Psychopathic Traits Inventory), the Psychopathic Personality Inventory (PPI) and the Triarchic Psychopathy Measure (TriPM) have been derived from another theoretical conceptualization of psychopathy that emphasizes the role of low anxiety. While it may be suggested that these measures have construct validity based on their associations with various external correlates, the precise nature of these associations is ambiguous due to evidence of problematic factor structures and the paucity of rigorous research examining latent structure and item-to-factor relations. As the PCL scales have accumulated extensive validation, it is important to consider the associations the PPI and TriPM have with the PCL-R as well as the coherence of the latent structure of these measures.

Concerns about the structure and construct validity of the PPI and its revision have been raised. The PPI is a 187-item measure consisting of eight subscales, seven of which are thought to be loaded onto two factors termed *fearless dominance* (FD) and *self-centered impulsivity*, which are believed to be associated with Factor 1 and Factor 2 of the PCL-R, respectively. However, FD and PCL-R Factor 1 share only 4–5% of variance, the FD factor has demonstrated opposing relationships with a number of external correlates, and the scales that comprise FD lack sensitivity in discriminating individuals with psychopathy from those without psychopathy from community and offender samples. In addition, researchers have found that the subscales of the PPI lack item homogeneity and the

two-factor model to be an untenable model. Taken together, the psychometric properties of the PPI introduce ambiguity to its interpretation, which attenuates the validity of the instrument.

The TriPM has demonstrated notable statistical issues that warrant attention. A 58-item self-report measure, the TriPM, conceptualizes psychopathy as a compound condition that emerges from interactions among three trait domains: boldness, disinhibition, and meanness. Although these three domains have been proposed to be elemental *building blocks* of psychopathy, item-level analyses have called this into question. Researchers have found poor fit for the TriPM three-factor structure due to the presence of subfactors nested within the three trait domains, with differential correlations among the subfactors and with external correlates. This pattern indicates that correlations between the three factors of the TriPM and other constructs will be imprecise due to the lack of item homogeneity and differential subfactor associations. With regard to construct validity, the TriPM domains evidence low to moderately low correlations with multiple facets of the PCL-R except the affective domain, which correlates with none of the TriPM traits. This pattern illustrates that the three proposed TriPM domains are multidimensional and may not assess psychopathy with the specificity demonstrated by PCL-R four-factor model.

Limitations and Future Directions

The SRP may have some limitations. Self-report measures can be subjected to dishonest responding or lack of insight. However, studies have found that psychopaths do not engage in impression management when completing self-report measures with no secondary gain. Future research should directly compare the statistical properties of the SRP with other SRP measures to see whether they are assessing the same construct. The SRP, with its robust relationship with the PCL-R and mathematically sound latent structure, is an ideal research tool for investigating psychopathy in a wide variety of samples.

SELF-REPORTS AND QUESTIONNAIRES

Self-reports and questionnaires can be used by qualified evaluators who conduct assessments for the criminal justice system. These evaluators are expected to employ objective, reliable, and valid self-reports and questionnaires that meet rigorous test development and scientific standards. The purpose of assessments for the criminal justice system is to aid triers of fact (e.g., judge, jury) in responding to specific legal questions. Legal questions typically involve the evaluation of competencies (e.g., competency to stand trial [CST]); criminal responsibility (e.g., mental state at the time of the offense); and sentencing, parole, or release (e.g., dangerousness). Although self-reports and questionnaires offer a number of advantages, they also have limitations that may compromise their validity. This entry addresses the value and limitations of self-reports and questionnaires and

then examines the specific self-reporting tools used in the criminal justice system: clinical assessment instruments (CAIs), forensically relevant instruments (FRIs), and forensic assessment instruments (FAIs).

Advantages and Disadvantages of Self-Report Measures

Perhaps the most compelling value of self-report measures is that they give individuals an opportunity to report thoughts, feelings, sensations, and behaviors that may be difficult to observe publicly or that take place only in private. Checklists and questionnaires are standardized, efficient, inexpensive, and easy to score and interpret. Interviews are another form of self-report. Even though they are less efficient and require more training to administer compared with questionnaires, they have an advantage because the interviewer can probe responses to clarify meaning and interpretation.

A disadvantage of self-report measures is that they may not be credible or accurate. There are many reasons for this, ranging from unintentional memory lapses and distortions to deliberate deception for attention or secondary gain. *Malingering* is a form of intentional deception in which external incentives motivate an individual to purposely exaggerate or falsely claim to experience physical or psychological symptoms. Individuals may also purposely attempt to conceal genuine symptoms in order to appear psychologically healthy, a form of deception known as *dissimulation*. Other forms of deception may be less severe, but also threaten the validity of self-report. For instance, some individuals may simply be unwilling to reveal thoughts that they consider to be socially undesirable, while other self-reports may be invalidated by the tendency to respond to items in a similar way independently of their content (i.e., individuals may answer questions with an affirmative or a negative response, without regard to their actual preference or experience).

Concerns Regarding Self-Report in the Criminal Justice System

There are a number of disadvantages associated with self-reports that are especially problematic in

the criminal justice system. Individuals involved within this system are advised that their disclosures cannot be kept confidential. Although constitutional safeguards protect an individual against self-incrimination, there are also other reasons that individuals may resist honest self-disclosures. The high stakes of criminal proceedings may motivate dishonesty in order to avoid conviction, reduce culpability with an insanity defense, seek a more lenient sentence, or gain admission to a psychiatric hospital. The potential for these secondary gains makes malingering a concern when considering individuals involved with the legal system. There are two types of malingering that may invalidate an individual's self-report: (1) grossly exaggerating or fabricating psychiatric symptoms and (2) feigning intellectual or cognitive deficits.

Malingering of psychiatric symptoms may be most commonly observed among individuals who are seeking an insanity defense, more lenient sentencing, or transfer to a psychiatric facility. Richard Rogers has provided the most comprehensive framework for evaluating malingering in the context of psychiatric symptoms. Within this framework, malingering is suspected when someone displays patterns of symptom endorsement that have certain characteristics. These patterns can include a frequent endorsement of obvious, extremely severe and/or rare symptoms; an endorsement of symptoms that have an outrageous or fantastic quality (e.g., honeybees command the individual to kill the president); or an endorsement of symptoms that represent misconceptions about mental illness (e.g., schizophrenia means having two personalities). Patterns can also include pairing unlikely symptoms (e.g., "I sweat when I hear voices") and random or indiscriminate responses. Malingering may also be suspected when an individual's self-report does not match clinical observations or collateral information.

Feigning intellectual or cognitive deficits may be observed among individuals undergoing competency evaluations, who may want to show evidence of intellectual disability, memory problems, or brain injury. In this form of malingering, a person tries to persuade the evaluator that low ability or poor performance is a genuine representation of his or her best efforts. Individuals who feign cognitive impairment typically show distinct patterns of responding to test items that vary in

the level of difficulty. Honest responders are expected to answer easy test items correctly, but they are not expected to perform much better than chance on difficult test items. In contrast, individuals suspected of cognitive malingering do not usually consider item difficulty when deciding which test questions to answer incorrectly. As a result, these individuals are more likely to score incorrectly on easy test items that even the most impaired individuals answer correctly, to score below what one would expect based on chance alone, or to show fewer mistakes on difficult test items compared with easy ones.

As understanding of malingering has grown, so too have efforts to successfully deceive evaluators and misrepresent impairments. These efforts include coaching examinees so that they can deceive the evaluator to avoid being suspected of malingering. Specifically, examinees may be educated about psychiatric symptoms or cognitive impairments, as well as methods used to differentiate an authentic presentation from a fabricated one. Research suggests that it is difficult to coach defendants on specific psychiatric symptom presentation (i.e., even with knowledge of bona fide psychiatric symptoms, individuals cannot successfully present themselves as experiencing a genuine psychiatric condition). In contrast, coaching on intellectual or memory impairments related to brain injury or intellectual disability has shown some success in enabling individuals to avoid detection.

Self-Report in the Criminal Justice System

Despite concerns about self-report, a number of self-report assessments may be used for evaluations related to legal questions in the criminal justice system, particularly if they are accompanied by an assessment of malingering or other threats to valid disclosures. Experts have divided these assessments into three categories: CAIs, FRIs, and FAIs. CAIs assess general clinical constructs, such as intelligence, psychiatric symptoms, and personality. This category of instruments is least likely to be relevant because of its broad scope and variable relevance to specific legal questions. They are typically used to inform treatment recommendations that may be part of a sentencing evaluation or to provide evidence of psychiatric

disorder or intellectual disability that may be relevant for evaluations of competency or criminal responsibility. FRIs also assess general constructs; however, these constructs have more direct relevance to legal questions that arise in the criminal justice system. For instance, violence risk assessment and indicators of psychopathy may be especially important considerations for evaluating dangerousness and risk for recidivism, which are important for legal decisions. The assessment of malingering also falls into this category. In contrast to CAIs and FRIs, FAIs are specifically designed for use in the legal process. A comprehensive review of CAIs, FRIs, and FAIs exceeds the scope of this entry; however, several commonly used, psychometrically sound, and empirically validated instruments are summarized in the following sections.

CAIs

Self-report assessments of personality, intelligence, and psychiatric disorders are among the most commonly evaluated constructs in assessments conducted within the criminal justice system. The most widely used self-report questionnaires of personality and psychiatric symptoms in the United States are the Minnesota Multiphasic Personality Inventory-2, Millon Clinical Multiaxial Inventory-III, and the Personality Assessment Inventory. Each of these inventories has been found to be reliable and valid with established norms. They all also include validity scales to evaluate potential sources of invalid responding due to missing information, indiscriminate responding, or response styles, such as acquiescence (i.e., yea-saying). Elevated scores on validity scales may also suggest efforts to intentionally overreport, exaggerate, or fabricate personality or psychiatric impairment or, conversely, to minimize or deny such impairment and present in a socially desirable manner. However, validity scales on the Minnesota Multiphasic Personality Inventory-2, Millon Clinical Multiaxial Inventory-III, and Personality Assessment Inventory are not definitive tests of malingering or dissimulation.

Self-report of psychiatric symptoms can be obtained through an interview or a questionnaire. Two commonly used interviews include the Structured Clinical Interview for Diagnostic and

Statistical Manual of Mental Disorders, which is a reliable and valid interview guide for establishing Diagnostic and Statistical Manual of Mental Disorders psychiatric diagnoses, and the Brief Psychiatric Rating Scale, which is another interview guide that is used to assess positive, negative, and affective symptoms of individuals who have psychotic disorders. There are dozens of specific checklists and questionnaires that can also be used to evaluate the severity of specific symptom clusters or diagnostic categories (e.g., Symptom Checklist 90-Revised). Unlike the personality inventories, however, there is no systematic and objective method for scoring the validity of these interviews and questionnaires.

Forensically Relevant Inventories

Psychopathy is considered to be a personality disorder that is characterized by persistent antisocial tendencies, a lack of empathy and remorse, deception, and impulsive and irresponsible behavior. Given the high co-occurrence of psychopathy with criminal behavior, its assessment has obvious relevance to predicting the likelihood of criminal reoffense and rehabilitation. Beginning in the 1970s, Robert D. Hare developed the Hare Psychopathy Checklist-Revised (PCL-R) to evaluate this set of personality features using a semi-structured clinical interview and a review of records. The PCL-R is considered to be the general standard for evaluating psychopathy. Its reliability and validity are buttressed by decades of rigorous empirical work. A number of self-report questionnaires have also been established to measure psychopathy. Unfortunately, research has shown that these questionnaires are highly susceptible to dissimulation; examinees appear to be able to easily mask their psychopathy. Moreover, self-report questionnaires show only moderate convergence with the PCL-R. Other risk assessment strategies rely heavily on review of official arrest records and other related documents.

Although self-reports and questionnaires are suspect in known offender populations, one self-report questionnaire has shown promise for predicting violent and nonviolent reoffense over a 5-year period: the Self-Appraisal Questionnaire. On this questionnaire, respondents answer questions about their criminal tendencies, behavior

problems, alcohol/drug abuse, anger, antisocial personality, criminal history, and antisocial associates. It has been shown to predict reoffense as well or better than other established measures, such as the PCL-R. It can also discriminate well among individuals at low, medium, and high levels of risk of violent and general criminal reoffense. Still, when it comes to risk and violence prediction, self-reports are not usually the most preferred approach.

Although many questionnaires include validity scales to evaluate response styles and intentional symptom exaggeration or fabrication, there are several self-report interviews and questionnaires that are specifically designed to detect psychiatric or cognitive malingering. These include the Structured Interview of Reported Symptoms, the Miller Forensic Assessment of Symptoms Test, Test of Memory Malingering, and the Rey 15-Item Memory Test. Each of these self-report instruments has well-established reliability and validity.

Forensic Assessment Inventories

Increasingly, self-reports and questionnaires have been used to evaluate competencies of individuals involved with the criminal justice system. The most well-established area of competence evaluation is CST. Although some evaluators use CAIs or FRIs when evaluating competency, the usefulness of these tools is limited because they do not provide specific information relevant to legal elements of competency. Since the 1970s, investigators have developed the Competency to Stand Trial Assessment Instrument and the Georgia Court Competency Test, interviews that explicitly evaluate the legal elements relevant to CST-related questions. Self-report questionnaires have also been developed to evaluate CST, with generally acceptable psychometric properties.

Practical Recommendations

There are several considerations when it comes to the use of self-reports and questionnaires in the criminal justice system. First, the measures must meet rigorous scientific standards for reliability and validity. Second, there must be a strategy for evaluating the credibility and accuracy of the individual's answers in order to rule out response

biases (e.g., random response, yea- or nay-saying, and social desirability) as well as deliberate falsification or exaggeration. Third, self-report should be supplemented with collateral information from other informants and with a review of official records. Doing so will provide valuable, accurate, and objective information to decision makers in the criminal justice system.

SENTENCING

Sentencing refers to a sanction or punishment imposed for the conviction of a criminal act. Sentencing decisions are generally made by the presiding judge and can take place in federal, state, or local courts. There are typically two types of sentences that can be imposed: custodial and noncustodial sentences. Each type of sentence can vary greatly, depending on many legal and extralegal factors. Since the 1970s, guidelines and reforms have been implemented to reduce judicial discretion and disparities in sentencing. This entry focuses on sentencing in the United States.

Sentencing Philosophies

Many common philosophies exist regarding the purpose of sentencing an individual for a crime that he or she committed. These philosophies range from attempting to change the behavior of the specific criminal before and after a crime was committed, to outright punishment for engaging in crime. Sentencing philosophies include retribution, incapacitation, rehabilitation, and deterrence.

Retribution refers to punishing an individual based on the crime that he/she committed. The sentence imposed under this philosophy must be proportionate to the crime that was committed. Retribution serves no greater purpose than to punish an individual for committing a crime.

Incapacitation is used as a sentencing philosophy to restrict an individual's ability to engage in crime by incapacitating the individual. Incapacitation can be used to protect the greater good of society.

Rehabilitation is guided by the notion that an individual should only receive enough punishment to alter the individual's future behavior. Rehabilitation as a sentencing philosophy is tailored to a component of individualized justice.

Deterrence is used to discourage the individual from engaging in future crime with fear of future punishments. Deterrence is also used to dissuade the general public from engaging in criminal behavior through fear of likely penalties or sanctions that would be imposed if caught committing a crime.

Types of Sentences

A sentence for the violation of a criminal code can be custodial and/or noncustodial. Custodial sentences are punishments that require that the defendant be remanded to prison, jail, or some other types of closed institution where the defendant will remain for the duration of the sentence. With some exceptions, misdemeanor charges can result in a jail sentence of up to 1 year, while felony charges result in prison sentences of longer than 1 year. Noncustodial sentences include probation, suspended execution/imposition of sentence, and fines. In some instances, defendants may receive a sentence that includes both custodial and noncustodial components. For instance, a defendant may receive a jail sentence and a fine or a short jail sentence followed by a term of probation. The type of sentence imposed can vary greatly based on legal factors, such as crime severity and defendant's prior record, as well as extralegal factors, such as the defendant's age.

Sentencing Systems

Two main systems can account for the structure of sentencing policies in the United States, each of which is based on a different theoretical approach about the purpose of punishment. The two systems include indeterminate and determinate sentencing. Until the mid-1970s, most states followed the indeterminate approach. Indeterminate sentencing systems are rooted in the notion of rehabilitation and individualized justice, leaving the time that will actually be served on the sentence to the discretion of judges and parole boards. In this approach, judges have great discretion on the sentence length handed down, so long as the upper limit of the sentence does not violate previously established maximum penalties. For example, a judge may impose a sentence of 2–8 years for a defendant charged with a felony that has a maximum penalty of 10 years. The time then served on the sentence is at the discretion of a parole board. A parole board may deem the defendant rehabilitated after 2 years but can also deny release and make a defendant remain incapacitated until the upper limit of their sentence has been served. Since the 1970s, indeterminate sentencing has been criticized for being applied indiscriminately, leading to disparities in sentencing as a result.

During the 1970s, backlash about the effectiveness of indeterminate sentencing and criticism about the ability of prisons to rehabilitate offenders led many states to abandon indeterminate sentencing systems for determinate, or *fixed*, sentencing schemes. Determinate sentencing systems eliminated parole boards and placed the decision of sentence lengths entirely at the control of judges. A sentence that is set at 12 years would have to be served out entirely, minus any good time credits. Under the determinate sentencing approach, the purpose of punishment shifts from rehabilitation and is placed on the notion of incapacitation. Sentencing under this scheme is more about holding and punishing offenders, rather than treating prisoners to reduce future criminal behavior. A major criticism of determinate sentencing systems is the lack of motivation it provided for inmates to improve themselves. Since rehabilitation was no longer the guiding philosophy behind sentencing, inmates who tried to improve themselves through education or training, for example, would spend the same amount of time incarcerated as those who did nothing to improve themselves. A second criticism of determinate sentencing laws is the inability of the criminal justice system to oversee the behavior of offenders once they are released, since parole is no longer an option.

Sentencing Guidelines

The vast amount of discretion held by judges and parole boards under the indeterminate and determinate sentencing systems led many states in the early 1980s to establish sentencing guidelines to limit discretion and disparities. Many of these guidelines are outlined by state-sponsored sentencing commissions. Although there was a push for all states to establish permanent sentencing commissions, only about half did so and many have been dismantled. As of 2007, there were 17 permanent sentencing commissions in the United States. Sentencing commissions are made up of many actors of the criminal justice system, such as prosecutors, judges, and defense attorneys. The primary purpose of sentencing commissions is to draft sentencing guidelines, publish related reports, and amend any sentencing guidelines as needed.

Following the role of some states, the U.S. Congress passed the Sentencing Reform Act in 1984,

which went into effect on November 1, 1987, that established federal sentencing guidelines. Sentencing guidelines do not entirely remove discretion from the judges but provide a much more narrow range of possible sanctions for a crime. Sentencing guidelines rely on the current charge that a defendant is facing, in combination with the defendant's criminal history. Based on these two components, guidelines would provide judges with an acceptable sentence range to be imposed. When judges depart from the established sentencing guidelines, they are required to provide justification for the departure.

In 2005, two Supreme Court decisions changed the way that sentencing guidelines could be implemented. *United States v. Booker* and *United States v. Fanfan* both challenged the factors that judges could take into account when making sentencing decisions. The U.S. Supreme Court ruled that sentencing guidelines could act as a recommendation template for judges, but that guidelines could not be used to definitively restrict criminal sentences. Both decisions were meant to reduce disparity in sentencing but have been found to have the opposite effect and led to increased disparities based on the offender's characteristics.

Other Sentencing Systems

Sentencing in the United States has also been influenced by other sentencing schemes, including mandatory minimum sentencing and habitual offender legislation. Mandatory minimum sentences impose a fixed penalty, target specific crimes, and do not allow judges to take into account mitigating factors when deciding punishments. As of 2010, there were over 195 federal offenses that had mandatory minimum sentences. While mandatory minimum sentences apply to a wide range of crimes, they are more commonly associated with sentences for drug crimes. For example, the Fair Sentencing Act that was passed in 2010 imposed an 18:1 differential for powder cocaine and crack. This means that the sentence for having 1 gram of crack will be equivalent to being charged with possession of 18 grams of powder cocaine.

Habitual offender sentencing laws target defendants who are charged with similar crimes on multiple occasions. Habitual offender laws allow judges to hand down increased sanctions each time the defendant is sentenced. Three-strikes

legislation is an often-imposed type of habitual offender law. *Three strikes* was initially implemented in Washington in 1993 and was adopted in 24 other states within the next year. Three-strikes laws are meant to provide long-term sentences for individuals charged with a third violent or serious felony.

There are widely held criticisms regarding mandatory minimum sentences and habitual offender legislation. The design of the policies still allows for a great deal of discretion by both judges and prosecutors, leading to differential treatment of offenders charged with similar crimes. Prosecutors may choose to reduce the charge of the crime to bypass the legislation or to coerce a guilty plea. Another criticism is the fact that these sentencing policies may lead to relatively low-level offenders, who pose little risk of reoffending, being incarcerated for prolonged periods of time. In general, mandatory minimum sentencing and habitual offender laws have been applied inconsistently and have led to sentencing disparities.

Results of Sentencing Policies

The aftermath of the shifts in sentencing policies in the United States has led to several consequences that affect society. One of the major costs of sentencing policies is the growth in incarceration rates in the United States. Sentencing policies were enacted as a response to the rise in violent crime experienced throughout the 1970s and 1980s, leading to more defendants being incarcerated. Despite the decline in violent crime during the 1990s, more punitive sentencing policies were continued to be implemented and enforced. This has resulted in an incarceration rate much higher than any other developed nation. In 2016, prisons in the United States held more than 655 inmates per 100,000 people. Sentencing policies have further resulted in inmates being incarcerated for much longer periods, leading to an aging process in U.S. prisons. Habitual offender laws, for instance, have resulted in low-risk elderly offenders to be required to remain in prison, despite the decreased likelihood of recidivism.

Another result of sentencing policies that afforded great discretion to judges and prosecutors at the charging and sentencing phases of criminal case processes has led to pronounced disparities in

the application of sentencing. Many of the sentencing policies that have been implemented in the United States are tied to specific crimes, which are generally highly correlated with race. It is argued that even when taking into account criminal involvement and many other legal factors, racial minorities are much more likely to be sentenced to prison and to receive longer sentences.

SEQUENTIAL INTERCEPT MODEL

The Sequential Intercept Model (SIM) is a conceptual framework that addresses the overrepresentation of individuals with serious mental illness in the criminal justice system. Due to a lack of access to community mental health services, individuals

with serious mental illness are significantly more likely to be arrested and detained for long periods of time compared with those without serious mental illness. The goals of the SIM are to prevent individuals with serious mental illness from being arrested and jailed, provide them with prompt and easy access to treatment services, limit the duration that they spend in the criminal justice system, provide linkages to community treatment services, and decrease recidivism. Therefore, the SIM identifies five potential points of interception of and intervention for individuals with serious mental illness along the criminal justice continuum. Provided that a jurisdiction has interventions at multiple intercepts, the intercepts are designed to act as a filter, with decreasing numbers of individuals needing to be served at each intercept. This entry provides an overview of the SIM intercepts.

Intercept 1: Law Enforcement and Emergency Services

In an era of deinstitutionalization, law enforcement and emergency services personnel are often the first point of contact for individuals with mental health emergencies. Police officers have discretion in deciding what course of action to take when they encounter individuals in mental health crisis, but a lack of crisis training and knowledge of available mental health resources often leads officers to believe that arrest is the only option available. Therefore, Intercept 1 is focused on developing strategies to help law enforcement officers deal effectively with individuals in mental health crisis. Such strategies may include employing a mobile crisis team composed of mental health professionals to consult with officers either in person or remotely while officers are in the field or providing officers with specialized mental health training to prepare them to respond to calls with individuals in mental health crisis and to refer them to appropriate services in lieu of arrest.

Intercept 2: Initial Hearings and Initial Detention

Intercept 2 focuses on postarrest diversion. Though preferable, it is unrealistic to think that police will always be able to successfully refer individuals with serious mental illness to appropriate services;

it is inevitable that some of those individuals will be arrested. At this stage, individuals with serious mental illness who have been charged with less serious offenses may be candidates for diversion to treatment in lieu of prosecution or incarceration. Such diversion programs include having court-employed mental health workers assess individuals for serious mental illness and offer recommendations for treatment or having courts forge relationships with community mental health resources to conduct assessments and identify and provide linkage to appropriate treatment services.

Intercept 3: Jails and Courts

The focus of the third intercept is on jails and courts. This is the last intercept where individuals with serious mental illness can be diverted from standard criminal justice processing to community-based alternatives. The primary alternatives at this stage are problem-solving courts. Although there are many types of problem-solving courts (e.g., drug courts, mental health courts), only a few types have been empirically examined, with drug courts being the most rigorously and extensively researched. For over two decades, drug courts have been providing treatment services and judicial supervision to individuals struggling with addiction and substance use. Drug courts provide resources, supervisors, and services to address criminological risk factors associated with substance use and criminal activity. This strategy provides offenders with serious mental illness with an opportunity to obtain the treatment services they need, while simultaneously keeping them out of the criminal justice system. A large body of research has shown that drug courts significantly decrease relapse and recidivism in a cost-effective manner.

Intercept 4: Reentry From Jails and Prisons

The fourth intercept of the SIM targets reentry. Individuals with severe mental illness are vastly overrepresented in the criminal justice system, and the recidivism rates for these offenders are higher than those of offenders without serious mental illness. The fourth intercept was developed to help

identify offenders with serious mental illness and provide them with an effective reentry program. A collaboration between the criminal justice system and community-based providers (i.e., mental health and substance abuse clinics) is required to address the different risks, needs, and responsivity of offenders returning from jail or prison. The most widely used theoretical framework for reentry is the Risk-Need-Responsivity model. This model calls for an assessment of an individual's risk of reoffending, identification of his or her current criminogenic needs and appropriate interventions, and tailoring those interventions according to the individual's learning style and motivation levels.

Intercept 5: Community Corrections and Support

The fifth intercept targets offenders with serious mental illness who are on parole or probation. Because these offenders are deeply entrenched in the criminal justice system, a balance of mental health and criminal justice services is necessary to reduce recidivism. To accomplish this goal, specialty mental health probation and parole programs have been developed. These programs provide mental health training to parole/probation officers and reduce overall caseloads for parole/probation officers. Additionally, Forensic Assertive Community Treatment, a derivative of Assertive Community Treatment, can be used in conjunction with standard parole/probation services to help provide mental health treatment. Forensic Assertive Community Treatment involves the use of a multidisciplinary team (e.g., mental health, medical, substance abuse counseling), smaller caseloads than those in traditional probation, and frequent contact for individuals with previous criminal justice involvement. Among other roles, Forensic Assertive Community Treatment provides services including assistance with housing, transportation to parole meetings, and community-based treatment, in an effort to prevent individuals from having further involvement with the criminal justice system. Focusing on criminogenic needs or mental health symptoms alone does not effectively reduce recidivism, but targeting both domains and providing adequate community support have been shown to lower

recidivism rates among offenders with serious mental illness.

SERIAL MURDER

Serial murder is a form of aberrant violent crime that, in simple terms, can be characterized by the commission of multiple murders perpetrated at intervening periods of time by the same offender or offenders. In comparison with other modes of crime and even other forms of homicide, the prevalence of serial murder is very rare. Cases of serial murder have been recorded throughout history and across most nations in the world. Despite the comparatively infrequent occurrence of serial murders, such crimes nonetheless attract a disproportionate notoriety, largely due to the numerous popular and sensationalistic media depictions of such crimes. The police investigation of serial murder is often difficult because criminological patterns typically observed in the perpetration of murders are often absent in the circumstance of serial murder. Nonetheless, specialized mechanisms such as computerized crime-tracking databases and criminal profiling have been developed to augment law enforcement responses to serial murder.

The Concept of Serial Murder and Its Definitional Problems

Although there appears to be an almost universal colloquial recognition of the term *serial murder*, the underlying concept of what precisely constitutes serial murder is not an easily defined issue. Essentially, when the detailed examination of this point is undertaken, it becomes apparent that serial murder does not actually reflect a singular construct but instead is better understood as a multifaceted phenomenon wherein there exist many different forms of serial murder that can be perpetrated for disparate reasons. To appreciate some of these issues and thus the complexities inherent to the diversity surrounding serial murder, some of the problems associated with defining it should be considered.

The term *serial murder* was originally coined to describe the sequential perpetration of multiple murders by the same offender or offenders. From the outset, even this very early definition embodies a number of potentially complicated explicit and implicit conceptual factors. Some examples of the explicit features include the recidivistic nature of the crimes (i.e., conveyed by multiple victims) as well as the time interval between the various murders. With respect to implicit features, there are the underlying motivational factors and drives, which account for the aforementioned explicit features and thus markedly differentiate these murders from more common forms of homicide.

Starting with the seemingly elementary issue of how many murders need to be committed before the crimes can collectively be classified as *serial* in nature has been the source of debate, with arguments ranging from a single murder being sufficient to a minimum of five murders. These differences are typically related to circumstantial factors that can influence the classification of the crime. For example, if an offender is apprehended immediately after his or her first murder but, given the opportunity, would have continued to commit further murders, does this exclude the offender from being classified as a serial murderer? Alternatively, if due to available evidence an offender is only convicted of a single murder although it is likely that he or she is responsible for many others, does this circumstance preclude classification as a serial murderer? Similarly, the time interval between murders has proven to

be an equally controversial issue as other forms of murder such as mass shootings or murders committed by professional assassins feature multiple victims whose murders are often separated by time intervals.

Underpinning all of these explicit factors are motivational dynamics, psychological mechanisms, and possible psychopathologies that might explain why these murders are being perpetrated. Once again, a gamut of different factors may be in operation which may account for multiple different forms of serial murder. For example, some murders are attributable to the operation of pathological sexual drives wherein a combination of fantasy mechanisms, sexual sadism, and fetishes are operating within the offender. Alternatively, some offenders are driven by an extreme hatred of some identified type or class of individual and set about murdering those people, and no overt element of sexuality underpins the murders. As a consequence of these contentious conceptual issues, *serial murder* should ideally be viewed as a simplistic term used in colloquial parlance to describe the occurrence of aberrant violent murders.

Police Response and Investigation of Serial Murders

As serial murders often do not feature criminological variables typically encountered in the perpetration of more common forms of murder (e.g., a readily identifiable nexus between the victim and the offender), a number of mechanisms have been specifically developed to assist police with their investigations. Possibly the two most prominent are violent crime databases and the technique of criminal profiling. One of the preliminary problems confronted by law enforcement when investigating serial murder is its actual identification. While the discovery of murder victims per se does not necessarily pose a significant investigative conundrum, the determination as to whether murder victims found at differing locations and at differing points in time are indeed related in terms of having been murdered by the same offender can prove to be a difficult task. To counteract the problems associated with the sheer volume of recorded crimes as well as legal jurisdictional boundaries that may hinder the sharing of information among law enforcement operatives,

computer databases have been developed. These systems collate and analyze recorded murders to determine whether behavioral similarities exist that suggests that two or more crimes within the database may have been committed by the same offender and thus related in terms of being suggestive of a serial murderer.

Another mechanism developed to assist with the investigation of serial murders is the technique of criminal profiling whereby behaviors apparent in various murders are analyzed for the purpose of developing a template of probable characteristics inherent to the offender or offenders of the murders. With the information contained in a *profile*, police investigators can prioritize their inquiries with any preexisting suspects. Alternatively, information from a criminal profile can be used as a means of potentially generating new lines of investigation. For example, a criminal profile may indicate that the probable offender is likely to possess an interest in a specific hobby, and equipped with this information, police may make inquiries of various clubs associated with the identified hobby.

SERVICES MATCHING INSTRUMENT (SMI)

Many assessments of mental illness (e.g., symptom checklists, diagnostic oriented symptom assessment) and criminal risk (e.g., level of criminal risk, criminal thinking) exist independently; however, the SMI is the first measure to simultaneously

assess both symptoms of mental illness and criminal risk in one measure. Using a multifaceted approach to improved mental health functioning, reduced criminal risk, and reductions in psychiatric and criminal recidivism, specific constructs were identified as influential to the justice involved person with mental illness functioning (i.e., symptoms of mental illness, substance abuse, resilience, social support and occupational functioning, problem-solving skills, antisocial attitudes, antisocial associates). Items were then generated by the test developers to assess these target areas. This entry provides an overview of the SMI, exploring the need for this tool, detailing its features, and discussing related study findings and future research areas.

Why the SMI Is Needed

Individuals with mental illness are overrepresented in the criminal justice system. Specifically, persons with mental illness are up to 3 times more likely to end up incarcerated than they are to end up receiving mental health services. Research has demonstrated that individuals with mental illness who are criminal justice involved share similar psychiatric symptoms with those with mental illness who are not criminal justice involved and share criminal risk factors with those who are incarcerated but not mentally ill. Thus, it stands to reason, when treating persons with mental illness within the criminal justice system, it is important to consider both the individual's co-occurring mental illness and criminogenic risk factors. Effective treatment of persons with mental illness within the criminal justice system begins with the assessment of these constructs, so professionals can gain a better understanding of the individual's specific treatment needs, decreasing the potential of reoffending.

A Closer Look at the SMI

The SMI consists of 94 theoretically derived items with a true or false response style. The 94 items produce eight theoretically derived clinical scales including psychiatric symptomology, criminal history, antisocial attitudes and associates, social networking, substance abuse, negative affect, social functioning, and traumatic history.

The psychiatric symptomology scale is an 18-item scale that asks about the presence of delusions, hallucinations (auditory and visual), and the individual's psychiatric history. These questions are aimed at assessing for the possibility of a psychotic disorder or related severe mental illness that may contribute to the risk of psychiatric recidivism. The criminal history scale is an 11-item scale that assesses for the occurrence of common criminal activities and behaviors. The theoretical underpinning of this scale supports the idea that the best predictor of future behavior is past behavior. The antisocial attitudes and associates scale is a 9-item scale that targets the individual's belief system, including his or her values and cognitions that disregard the rights of others and support a criminal lifestyle, and assesses the individual's social support network of criminal and noncriminal others. The social networking scale is composed of 9 items that focus on the individual's interpersonal functioning and ability to form and maintain healthy (i.e., prosocial) relationships. The substance abuse scale is a 9-item scale that assesses for the presence of alcohol- and drug-related disorders. The negative affect scale is a 15-item scale that assesses for the presence of persistent negative emotion and related depressive symptoms. The social functioning scale is a 12-item scale that evaluates the individual's ability to perform expected duties and contribute to society in a positive manner. Finally, the traumatic history scale is a 7-item scale that provides information about the individual's exposure to trauma to inform treatment (to allow for trauma-informed services), as well as a possible important target of treatment. The final four questions of the SMI form the infrequency scale that provides information about test-taking attitudes and screens for potential overreporting or exaggeration of symptoms and experiences.

It is hoped that this measure can provide clinicians with one self-report measure to determine clinical service needs to more efficiently match offenders with mental health and rehabilitation services. For example, if the SMI identified antisocial attitudes and associates as a potential problem area, the offender would be matched with appropriate services targeted at reducing criminal thinking and forming prosocial friendships.

Study Findings and Future Research

Initial research has focused on providing support for the internal consistency, test-retest reliability, and factor structure of the measure. With respect to internal consistency (i.e., how well the items on a scale measure the same trait), α values ranged from .767 to .937, suggesting strong cohesion of items within each subscale. The SMI also demonstrated a significant test-retest reliability (i.e., test of trait stability over time) over a 2-week time period ($r = .908$), an important issue given the purpose of this measure is to link offenders with clinical services. Research to date is promising, but ongoing and future research will focus on providing support for the validity (i.e., the degree to which a measure is testing what clinicians think it is) of the measure and confirming the proposed factor structure.

Given the overrepresentation of people with mental illness in the criminal justice system, but also the number of individuals in the mental health system that have criminal justice involvement, it is anticipated that this measure will be of clinical utility during all phases of assessment. For example, this measure can help identify areas of treatment need during initial mental health or criminal justice screenings or during the assessment intake when an individual is admitted to a new institution or program. The SMI may also be administered pretreatment and posttreatment to assess treatment change. Importantly, it is intended that the SMI will be helpful to mental health and criminal justice professionals working in correctional agencies (jail, prison, probation, parole), forensic mental health units, and general psychiatric facilities to more efficiently assess and subsequently guide clinical decision-making and case management strategies.

SEX OFFENDER RISK APPRAISAL GUIDE (SORAG)

The Sex Offender Risk Appraisal Guide (SORAG) is a 14-item static actuarial risk assessment tool developed to assess risk of general violence (sexual and nonsexual) with adult male sex offenders. After reviewing the development and content of the SORAG, this entry discusses its predictive accuracy, strengths, limitations, and applications and concludes with a look at a recent revision merging the SORAG with a companion measure.

Development and Item Content

The SORAG was developed in 1998 by Vernon Quinsey, Grant Harris, Marnie Rice, and Catherine Cormier at the Mental Health Centre Penetanguishene in Ontario, Canada, a maximum-security psychiatric facility. Although intended to be used with sex offenders, the broad scope of the SORAG is based on the premise that violence as an aggregate outcome is sufficiently serious to merit assessment. For instance, the public is no less deserving of protection from an individual who has committed a nonsexual homicide than an individual who has committed a sexual assault. Furthermore, there is evidence that men who commit sexual offenses (e.g., sexual assault of an adult woman, sexual abuse of a child) have some unique risk factors that set them apart from other violent offenders (e.g.,

deviant sexual interests, sexual offense history) which are predictive of violence and enough to justify the development of a separate scale.

The SORAG was originally developed on 288 adult male sex offenders from four independent samples who were released from Mental Health Centre Penetanguishene and followed up in the community. The rate of violent recidivism observed in the overall sample was 42% over 7 years and 58% over 10 years. The items for the SORAG were identified through statistical procedures aimed at identifying combinations of predictors that optimized the prediction of violence. In all, 14 variables that discriminated violent recidivists from nonrecidivists are listed in Table 1. The correlation for each individual item with binary violent recidivism (i.e., yes–no violently reoffended) is presented in Table 1, along with the weighting of each item.

Briefly, correlations are statistics ranging in value from -1.0 to $+1.0$ representing the strength of association between two variables. When a correlation is computed between one binary variable (i.e., a variable that can take one of only two values, such as inpatient or outpatient or criminally insane or not criminally insane) and another variable with a range of values, this is called a *point biserial correlation*. Point biserial correlations from $.10$ to $.23$ are considered small in magnitude, while those ranging from $.24$ to $.36$ are moderate and $.37$ and above are high. These 14 items were used as the foundation for developing the SORAG. After the best predicting items were identified, a technique known as *the Burgess method* was used to differentially weight predictor variables shown to successfully discriminate violent recidivists from nonrecidivists. For each category or value of a predictor demonstrating a 5% increase or decrease in recidivism from the overall rate, a weighting of $+1$ or -1 , respectively, is assigned. The weights are increased in either direction based on the degree of difference from the overall recidivism rate associated with a given category or value on a variable. In this manner, stronger predictors—that is, variables with the best discriminating power—were given the heaviest numerical weights (see Table 1). As the SORAG is part of a collection of instruments that were developed in a purely data-driven

Table 1 SORAG Items: Associations With Violent Recidivism and Range of Individual Weights

<i>Item</i>	<i>Correlation</i>	<i>Weights Range</i>
1. Lived with biological parents to age 16	.19	-2 to +3
2. Elementary school maladjustment	.18	-1 to +5
3. History of alcohol problems	.07	-1 to +2
4. Marital status	.18	-2 to +1
5. Prior nonviolent offenses	.10	-2 to +3
6. Prior violent offenses	.05	-1 to +6
7. Prior sexual offenses	.17	-1 to +5
8. Sex offenses against girls under age 14 only	.13	0 to +4
9. Failure on prior conditional release	.13	0 to +3
10. Age at index offense	.18	-5 to +2
11. <i>Diagnostic and Statistical Manual of Mental Disorders, Third Edition</i> personality disorder	.25	-2 to +3
12. <i>Diagnostic and Statistical Manual of Mental Disorders, Third Edition</i> schizophrenia	.10	-3 to +1
13. Phallometric test results	.14	-1 to +1
14. Psychopathy Checklist-Revised Score	.26	-5 to +12

Source: Quinsey et al. (2015, p. 138).

manner in the absence of theory, it is termed an *empirical actuarial* scale.

Once scored, the items are summed to generate an overall score that was associated with the probability of violent recidivism postrelease. With possible scores ranging from -26 to +51, the SORAG is scored in a manner such that higher scores were associated with increased violent recidivism and lower scores were associated with lower rates of future violence. The SORAG was then divided into nine score bands which were associated with different rates of violent recidivism over 7-year or 10-year follow-up. In 2013, the SORAG was renormed on a sample of 716 sex offenders with a minimum of 10-year follow-up. With a sample nearly triple the development sample, the bin sizes were also larger and more representative. For instance, Bin 9 in the construction sample had only five cases, while in the updated normative sample, it has 64 cases. Table 2 presents summary information on the nine SORAG risk bins, score range, the percentage of 10-year violent recidivism associated with bin membership, and the bin size (*n*) for each.

Table 2 SORAG Bins, Score Range, and Rates of 10-Year Violent Recidivism

Bin	SORAG Score Range	% Recidivism	<i>n</i>
1	<11	.18	39
2	-10 to -5	.25	63
3	-4 to +1	.38	93
4	+2 to +7	.44	100
5	+8 to +13	.56	106
6	+14 to +19	.62	86
7	+20 to +25	.73	93
8	+26 to +31	.72	72
9	>+32	.91	64

Source: Quinsey et al. (2015, p. 148).

Subsequent Validations

In the original development sample for the SORAG, the instrument demonstrated a strong predictive accuracy for future violence, with an area under the receiver operating curve (AUC) value of .75. With possible values ranging from 0 to 1, an AUC of .75 would be interpreted to mean there is a 75%

chance that a randomly selected violent recidivist had a higher SORAG score than that of a randomly selected nonrecidivist. Such an effect is considered to be large in magnitude and to represent high predictive accuracy. The authors noted that the SORAG was a weaker predictor of sexually motivated recidivism (being .05 to .15 lower in terms of AUC value), but that it continued to significantly predict this specific outcome.

Subsequent validations of the SORAG have reaffirmed its properties for predicting future sexual and general violence among sex offenders. Quantitative reviews of the SORAG, termed *meta-analysis*, have been conducted to examine how well the SORAG and its variants predict future violence postrelease among sexual offenders. A major meta-analysis published in 2009 of 118 recidivism prediction studies of men who committed sexual offenses generated support for the predictive properties of the tool. Specifically, AUC equivalents (converted from Cohen's *d*) were obtained for the prediction of sexual recidivism (AUC = .67, 12 studies), violent recidivism (AUC = .71, eight studies), and general recidivism (AUC = .72, eight studies). In the 2013 renorming of the SORAG on 716 sex offenders, the tool demonstrated very good predictive accuracy for violent recidivism (AUC = .73).

In all, the existing research to date has supported the predictive accuracy of the SORAG scores for the prediction of future sexual violence, general violence, and general criminal recidivism among adult male sex offenders.

Strengths, Limitations, and Applications

The SORAG is a fairly objective risk instrument to score that yields a high level of interrater agreement between independent raters, thus demonstrating high interrater reliability. It also has demonstrated high predictive accuracy overall for general violence among sex offenders and moderate-level accuracy for predicting sexually motivated recidivism. It is used frequently throughout the United States and in several countries internationally for assisting decision makers in making judgments about conditional release (e.g., parole boards) or sentencing (e.g., judges, review boards). As the SORAG is composed entirely of static items (i.e., historical and generally unchanging), however, it

cannot assess changes in risk from positive progress made in risk reduction treatment or resulting from other credible change agents (e.g., specialized treatment completion, improvement in supports, major deterioration in health). For this reason, there is justification to supplement the SORAG with other measures that assess dynamic (i.e., changeable) risk markers to inform decisions concerning sentencing or conditional release.

Moreover, the SORAG has received criticism on the basis of its normative sample: violent, mentally disordered, psychiatric patients. Arguments have been advanced that the recidivism rates and the weighting of the items may be less applicable to nonmentally disordered offenders in conventional justice settings (e.g., prison, probation); of note, however, many replications of the SORAG have been with sex offender samples across a range of correctional and forensic settings, supporting the generalizability of its predictive properties. Critics have cited additional concerns, however, with the representativeness and stability of the instrument's bin structure, for instance, containing some bins of extreme scores with small subgroups of men (e.g., Bin 9) associated with 100% recidivism. The revised 2013 norms address this concern with larger *ns*, a greater representation within each of the nine risk bins, and none of the bins reaching 100% recidivism, even for the most extreme scores over the longest follow-up periods.

Revision and New Validations

The 2013 renorming of the SORAG also saw the development of a revised tool intended to supplant the SORAG through merging its item content with a companion measure developed by the same research group to form the Violence Risk Appraisal Guide-Revised (VRAG-R). The VRAG-R was developed and validated on a sample of 1,261 violent offenders from previous studies with an extended follow-up and is intended for use with both sexual and nonsexual violent offenders. The VRAG-R is simplified in scoring, including no longer requiring the rating of diagnostic criteria and substituting the antisocial factor from the Psychopathy Checklist-Revised in place of the whole instrument. Validation research for the VRAG-R is promising (AUC = .76), and further research will be forthcoming.

Conclusions

The SORAG is an empirical actuarial risk assessment tool with a strong foundation of validity research supporting its predictive accuracy for general violence and sexually motivated violence with adult male sex offenders. In recent years, it has been merged with the VRAG, and the resulting instrument has been streamlined to create the VRAG-R, which has simplified scoring and demonstrated predictive accuracy for future violence among sexual and violent nonsexual offenders. Although the limitations inherent within any static tool apply no less to the SORAG, the tool enjoys a widespread and an international use to assist decision makers in sentencing and conditional release decisions to manage risk, prevent future violence, and enhance public safety.

SEX OFFENDER TREATMENT INTERVENTION AND PROGRESS SCALE (SOTIPS)

The SOTIPS is a statistically derived dynamic risk assessment instrument for adult males who have been convicted of sexually abusive behavior.

Mental health clinicians, correctional caseworkers, and probation and parole officers use the SOTIPS to assess an individual's sexual reoffense risk, treatment and supervision needs, and treatment progress. The SOTIPS is designed to be scored at the time an individual begins a treatment or supervision program and thereafter as frequently as every 6 months.

The SOTIPS surveys 16 potentially changeable domains (i.e., criminogenic needs or dynamic risk factors) that are related to risk of future sexual offending. The SOTIPS may be used alone or in conjunction with a static sexual offender risk assessment instrument, such as the Static-99R or the Vermont Assessment of Sex Offender Risk-2, which is composed of unchangeable risk factors. When used in conjunction with a static risk instrument, SOTIPS scores can be used to adjust baseline recidivism risk predictions. This entry explores the items on the SOTIPS and then explains the criteria for its use, the interpretation of scores, and how to implement this risk assessment tool.

SOTIPS Items

The 16 SOTIPS items are scored on a scale of 0–3, with higher scores indicating greater treatment need and dynamic risk. Most SOTIPS items are scored to reflect an individual's cognitive and behavioral functioning for the previous 6 months. SOTIPS items can be clustered into five conceptual categories: sexuality and risk responsibility, criminality, treatment and supervision cooperation, self-management, and social stability and supports.

Sexuality and Risk Responsibility

The sexuality and risk responsibility category contains 5 items related to sexuality and sexual abuser treatment motivation. The *Sexual Offense Responsibility* item measures the extent to which an individual internalizes responsibility for his sexual offending behavior. *Sexual Behavior* measures the proportion of the individual's nonabusive behavior to offense-supportive sexual behaviors during the previous 6 months. Offense-supportive behavior includes engaging in promiscuous sexual behavior, using pornography in violation of supervision or treatment rules, and

engaging in illegal sexual behavior. *Sexual attitude* addresses the cognitions and beliefs that drive sexually abusive behaviors, including viewing sexual urges as uncontrollable or viewing sexual activity with children as not harmful. *Sexual interest* quantifies the degree to which the individual's overall sexual interests focus on offense-related themes, including greater sexual interest in children or rape than interest in consensual sexual activity with consenting adults. *Sexual risk management* evaluates the individual's understanding of his risk factors for sexual reoffending and the adequacy of his plan and its implementation to manage his risk in the community.

Criminal Behavior

The second SOTIPS category contains 2 items that are related to antisocial behaviors and attitudes. *Criminal and rule-breaking behavior* quantifies behaviors associated with breaking criminal laws, not adhering to probation or parole conditions, or failing to abide by correctional facility rules. *Criminal and rule-breaking attitude* measures the extent of cognitions and beliefs supporting such behaviors (e.g., "It is only wrong if you get caught" and "Rules are made to be broken").

Treatment and Supervision Cooperation

The third SOTIPS category contains 3 items. The *stage of change* item evaluates an individual's engagement in the change process (i.e., whether he believes in the need to change to reduce risk to sexually reoffend, is ambivalent about change, is actively making changes, or is maintaining positive changes that he have already made). *Cooperation with treatment* and *cooperation with community supervision* evaluate the individual's adherence to the expectations of sexual offender treatment and community supervision, respectively.

Self-Management

The first self-management item is *emotion management*, which evaluates an individual's ability to manage intense emotional states (e.g., loneliness, anger, jealousy, and depression). *Problem-solving* concerns the individual's ability to consider problems rationally, develop prosocial plans of action, and successfully carry out plans to

resolve such problems. *Impulsivity* gauges the individual's overall ability to engage in behavior that is thoughtful, deliberate, and planned.

Social Supports and Stability

The final 3 items pertain to general social functioning and the capacity to lead a prosocial lifestyle. *Employment* quantifies an individual's ability to retain full-time employment or educational enrollment. *Residence* measures an individual's stability of and satisfaction with recent accommodations. *Social influence* weighs the impact, both positive and negative, of an individual's family, friends, and other associates on his behaviors. Positive family and friends support an individual's prosocial lifestyle. Negative family and friends are those who hold antisocial values, engage in crime or substance abuse, and otherwise do not model or support prosocial lifestyle.

Criteria for Use

The SOTIPS has been developed for use only with adult males who have been convicted of at least one qualifying sexual offense against an identified child or nonconsenting adult victim. The definition of a qualifying sexual offense is based on the Static-99R risk instrument criteria for category A offenses, which include rape, child molestation, and exhibitionism. The SOTIPS is not recommended for use with individuals who have been convicted of only Static-99R category B offenses, which are convictions for sexual behavior that is illegal but the parties were consenting or no identifiable victims were involved (e.g., possessing child pornography, engaging in consenting sexual behavior in a public place, soliciting a prostitute). In addition, the SOTIPS is not recommended for use with juvenile males or with female offenders of any age.

The SOTIPS is recommended for use with any adult male offender meeting the above criteria, regardless of intellectual capability. An earlier version of the SOTIPS, the Treatment Intervention Progress Scale for Sexual Abusers with Intellectual Disabilities, was adapted for use with individuals who have an intellectually disability.

The SOTIPS is most commonly used with individuals residing in the community. This typically involves individuals who are being supervised by

probation or parole officers, participating in outpatient sexual offender treatment, or both; rarely would SOTIPS be used for an individual in the community apart from community supervision or treatment. Residential application of the SOTIPS has been less thoroughly examined, but it can also be used with individuals in correctional facilities and other residential environments.

Since the SOTIPS is a dynamic risk instrument, it is designed to account for an individual's improving or worsening on potentially changeable risk factors (i.e., criminogenic needs). Thus, it is recommended that individuals be scored on the SOTIPS every 6 months. With only a few very specific exceptions that are detailed in scoring rules, information used in scoring is based on the individual's behavior during the 6 months prior to the SOTIPS evaluation.

Interpreting SOTIPS Scores

SOTIPS items are scored on a 4-point scale of 0–3. A score of 0 represents *no or minimal need for improvement*, 1 is *some need for improvement*, 2 is *considerable need for improvement*, and 3 represents *very considerable need for improvement*. The scores of the 16 items together form an aggregated score range of 0–48. This total score can be interpreted without further adjustment, which quantifies the overall level of treatment need and risk of future offending behavior. Alternatively, consecutive scores may also be clustered into relative risk/need categories, suggested as low (0–10), moderate (11–20), and high (21 and above) levels of treatment need and risk of recidivism. These categories may be used to inform general resource allocation or treatment dose within a population of individuals convicted of qualifying sexual offenses. Individuals with low treatment needs would receive no or minimal treatment services, and those with greater treatment needs would receive correspondingly greater amounts of treatment services.

Specific reoffense data, or norms, are provided by the SOTIPS developers or may be derived specifically with a population on which the SOTIPS is being used. Correct application of SOTIPS norms requires the user to evaluate the similarity of the normative sample characteristics with the characteristics of the offending individual's population. Developer-provided norms are designed to predict

the likelihood of a new offense 1 year and 3 years following SOTIPS scoring.

The SOTIPS can be used alone, but it is most commonly used in conjunction with a static risk instrument such as the Static-99R or the Vermont Assessment of Sex Offender Risk-2. Combined static–dynamic recidivism risk norms are commonly reported as an adjustment of the static risk level. A static risk level can be treated as an individual's *baseline* risk, with low dynamic risk suggesting that the overall risk level is below the static baseline and high dynamic risk suggesting an adjustment of the risk level above the baseline. Alternatively, combined static–dynamic risk information can be presented as a two-dimensional risk matrix, with each matrix cell representing a unique category of risk information. Although this provides more precise information, it is less efficiently employed.

Statistical Consideration With Repeated-Measures Risk Assessment

A dynamic measure that examines multiple points at which the offending individual may be evaluated is known as a *repeated-measures design*. The SOTIPS is designed to evaluate an individual's recidivism risk and treatment needs every 6 months, and no theoretical ceiling on how often it can be used has been established. Unlike static assessment methods, repeated-design assessments require additional methods for evaluation and implementation.

Analyses of predictive validity are of the foremost concern. The area under the receiver operating characteristic curve (AUC) statistic is commonly used in evaluating the accuracy of statistically derived risk measures such as the SOTIPS. Briefly, this statistic presents the probability that an individual's likelihood to reoffend is correctly identified (i.e., true positive) versus incorrectly identifying the individual as a potential recidivist (i.e., false positive). AUC values range from 0 to 1, with 0.5 representing chance-level prediction and 1 representing perfect prediction. In the case of the SOTIPS, multiple SOTIPS scorings recorded over time for those evaluated can be used to statistically evaluate its predictive accuracy using the AUC. An important consideration in such an evaluation is the value of the SOTIPS in combined static–dynamic assessment schemes over static-only assessments. In these

analyses, aggregating repeated SOTIPS scores from an evaluated person is preferable when combined with single-scored instruments such as the Static-99R. Such an implementation does show a slight incremental improvement in the AUC value over the Static-99R alone (AUC = .74 vs. AUC = .72). These AUC values represent moderate predictive validity and are similar to those of other sex offender risk assessment instruments.

SOTIPS as Part of Collaborative Treatment

Contemporary treatment planning methods favor a collaborative approach when working with individuals who have sexually offended. With guidance, clients in sexual offender treatment can effectively complete a SOTIPS evaluation. This exercise serves two functions: First, it can provide treatment professionals better insights into their patients' treatment needs, which may not be readily evident for the service provider. Second, it can better educate individuals who have sexually offended about the processes of assessment and treatment.

SEXUAL OFFENDER REGISTRIES

Among the diverse policies used worldwide to manage offenders convicted of sexual crimes in the community, sexual offender registries (SORs) are a common approach. SORs are databases of information pertaining to persons previously convicted of sexual offenses. The intention of SORs is to protect the public primarily by helping law enforcement monitor the whereabouts of identified sex offenders. In certain countries, information contained in these registries is also available to the public. Although SORs are generally developed in response to highly publicized and brutal sex crimes, there is little research evidence to support their efficacy, and there are also some documented challenges associated with SORs. This entry provides an overview of the purpose of and information contained in SORs, reviews the research on their efficacy and issues of concern, identifies their impact on offenders as well as associated collateral consequences, and discusses public support of SORs.

Overview of Sex Offender Registries

Researchers in the United States have investigated the development of sex offender policies, such as the sexual psychopath laws in the 1950s and sex

offender registration and notification policies ratified in the 1990s and 2000s. These researchers have noted that many of these policies have been instituted as a result of public panic and outcry, in response to highly publicized heinous crimes. In several countries, registries and other related policies have regularly been named after victims of tragic sexually violent crimes committed against children (e.g., Jacob and Megan's laws in the United States and Christopher's law in Canada). Many registries have primarily been enacted to keep track of persons convicted of crimes against children; however, registries are not necessarily restricted to child sexual offenders.

Purpose

The ultimate purpose of or justification for SORs is to protect the public and reduce sexual recidivism of habitual offenders. This goal is achieved in several ways: (1) helping law enforcement surveil known offenders, (2) providing law enforcement with up-to-date information in order to assist in resolving cases of a similar nature, and (3) in the case of public registries, heightening public awareness of sex offenders and providing information to communities that people can use to protect themselves and their families. Furthermore, registration also acts as a larger penalty for offenders convicted of sexual crimes and thus can also be considered a deterrent for those who have not committed a sexual offense.

Basics

Although the particulars of how offenders in different countries are placed on registries may differ, generally speaking, one must first be convicted of a registerable offense. The types of eligible offenses vary and can include both contact and noncontact sexual offenses. At a minimum, convictions for sexual offenses involving child victims and/or those involving violence would usually qualify an offender for registration.

Sex offenders have to remain on registries for a prespecified minimum period of time, which can range from several years (usually at least 5 or 10) to a lifetime; the time frame usually depends on the specific offense committed. SORs contain information on sex offenders who have completed

their sentence or who are serving the rest of their sentence in the community. Upon release/com-mencement of the community portion of their sentence, offenders are usually required to register themselves with local law enforcement as part of their sentencing conditions. Failure to register or to provide accurate and current information for the registry is also often considered a criminal offense and may result in additional penalties for these offenders (e.g., a fine or even additional jail time, depending on the jurisdiction). In some countries, after a certain minimum amount of time, offenders may be allowed to petition to be removed from the registry.

Information and Management

Information contained in registries varies depending on the jurisdiction but generally consists of the name, current address, and some description of the offenders' most recent offense and/or offending history. Registries also usually contain a photograph and descriptive information of the offender such as height, weight, hair color, and significant identifying characteristics (e.g., tattoos and/or birthmarks). Some registries may also contain DNA samples. For the most part, registries contain information on adult offenders, although depending on the jurisdiction there are also juvenile registries. In the United States, for example, persons as young as 14 years of age can be required to register.

SORs are typically managed by local and/or national law enforcement agencies. Public notification, access to SORs, and the amount of information provided to the public vary depending on the particular policy of each country. Public registries are usually available to local residents via the Internet, and public notification is usually accomplished via news media.

Global Overview

SORs have proliferated globally since the mid-1990s. Although registries have been in existence at the state level since the 1940s, the world's first national-level sex offender registration law, known as the *Jacob Wetterling Act*, passed in the United States in 1994. In the United States, additional policies have further combined registration and

notification: In 2006, the Adam Walsh Act, also known as the *Sex Offender Registration and Notification Act*, was enacted. Since 1994, approximately 30 other countries have enacted or are in the process of enacting similar sex offender registration and/or notification legislation at either the provincial/state or national level, including some of the following: Canada, Australia, France, Germany, Ireland, the United Kingdom, Jamaica, New Zealand, Portugal, Spain, India, Argentina, Kenya, South Africa, Trinidad and Tobago, South Korea, and Taiwan. Other countries, including some of the following—Belgium, Switzerland, Finland, Malaysia, Israel, and Hong Kong—have considered such policy but these laws have not passed, as of 2017. Depending on the country, registration and notification systems are one and the same, or they are separate policies.

Evidence for Efficacy and Issues of Concern

Researchers, predominately from the United States, have investigated the efficacy of sex offender registration and notification policies with disappointing results. U.S. researchers, in 2008, compared the incidence of sexual assaults across 10 U.S. states through a time series analysis in order to test if registration and notification laws reduce the overall incidence of rapes. This research found mixed results overall noting that the majority of states experienced no significant change in rates. Authors noted that the findings indicate these policies have little general deterrent effects.

U.S. researchers have also investigated the impact of the Adam Walsh Act, which provided a tiered method to reclassify registered offenders based on the particular offense committed (i.e., each tier corresponds to a specific registration duration as well as to the extent of registration updates required annually). In 2010, it was found that this new system resulted in a larger number of sex offenders classified as Tier 3 and thus requiring lifetime registration; this broader inclusion placed an unnecessary fiscal burden on the justice system, given the high cost of upkeep associated with the registry. Furthermore, placing more offenders within the registry at the highest tier may even have made it more challenging for law enforcement officials to discriminate among

registered offenders efficiently. Finally, this broader reclassification of sex offenders is in contrast to the available research evidence that suggests only the minority of sex offenders reoffend, and there is a limited group of offenders who are high risk. Most research to date does not provide supportive evidence for the use of sex offender registration and notification legislation to prevent sexual recidivism. There is currently no information regarding the actual performance of the Canadian SORs in terms of identifying and apprehending offenders sooner and/or decreasing recidivism.

Beyond the lack of evidence, researchers have also indicated that registries are ineffective because they are not comprehensive, and information is often incomplete or inaccurate. This is a result of the fact that most sexual crimes are unreported, offenders may not comply with requirements, plea bargains allow certain offenders to negotiate out of registering, and finally, this legislation focuses on offenses with stranger victims, which are relatively rare. Additionally, upkeep and maintenance of these registries are expensive.

Impact of Registration on Offenders

U.S. researchers in the mid- to late 2000s have investigated the impact of registration and public notification on sex offenders and found that offenders report a variety of issues as a result of having to register. Offenders reported experiencing serious social and economic consequences, including loss of friends, significant stress, stigma, discrimination and depression, relationship problems, job loss, and denial of housing. Some of these reported difficulties are risk factors associated with criminal recidivism. Notably, one 2007 study even found that registered sex offenders in the United States see potential for registration legislation to reduce reoffending; however, they have serious concerns about the efficacy and widespread application of such laws.

Less research on this topic has been conducted elsewhere in the world. Results from a small qualitative study completed in Canada in 2013 suggest that registered Canadian offenders did not find being on the registry too onerous, and over half of the sample reported that being on the registry had little to no impact on their ability to successfully reintegrate into the community. The major

problem reported about the registry was in regard to the extended length of reporting time (at minimum 10 years), which was seen as a barrier to successfully moving forward and desisting.

Research indicates that families and friends of registered offenders are also impacted negatively by registration policies in the United States, and in particular, as a result of the notification aspect. Financial and housing problems are notable negative consequences, in addition to the experience of harassment, threats, violence, and psychological stress.

Public Support for SORs

Although there are issues associated with SORs and there is a lack of evidence that registries impact recidivism, researchers have found that public support for such policy has been consistently high and that members of the public reported feeling safer having registries in place. Both in Canada and in the United States, the majority of the public surveyed in several studies was supportive of SOR legislation as well as public access to registries. Interestingly, U.S. researchers have found across several studies that the public still supports and desires SORs, and particularly public registries, even though they had never accessed nor had any intention of accessing such registries (2007, 2008, and 2011 study findings) and even after having been told there is a lack of scientific evidence to support their efficacy (2015 finding). This suggests that although sex offender registries have not been found to impact recidivism or public behavior, they hold high symbolic value in the eyes of the public.

Final Thoughts

SORs contain information on persons previously convicted of sex offenses and are intended to protect the public and reduce recidivism. Many countries worldwide have some sort of sex offender registration and/or notification policy in place, and the research to date suggests that the public does support SOR policy. Beyond the symbolic value of SORs, there is a lack of evidence supporting the impact of SORs on offender or public behavior. In addition, registries are costly, and public notification has resulted in sex offenders

facing additional barriers as they attempt to reintegrate into the community. Since there is limited research available regarding the impact of registries in terms of assisting law enforcement to solve similar crimes, continued evaluation of existing SORs and investment in SOR policy worldwide is warranted.

SEXUAL OFFENDERS

Sexual offenders are criminal offenders who have been found guilty of committing offenses that are sexual in nature. Sexual offenses cover a broad range of sexual behaviors that include child molestation, rape, sexual harassment, and the production or distribution of pornographic material involving children as subjects. Criminal sexual behaviors are nonconsensual (i.e., the victim is unwilling or is unable to consent to sexual activity). Victims can be unable to consent if they are too young, or if they are considered incapacitated due to alcohol, drugs, or a preexisting mental condition. All the following behaviors are examples of sexual crimes: an individual exposing his genitals at a public location, an individual using threats to impose sexual contact on another adult, a 20-year-old male engaging in sexual activity with his 14-year-old girlfriend, and the fondling of a child by an adult. If reported to the police, these behaviors can lead to criminal charges and conviction. The perpetrators of these acts are considered sexual offenders. This entry reviews the characteristics of criminal offenders who commit sexual offenses, the etiology of sexual offending and classification of offenders, the legal provisions specific to the management of sexual offenders, the assessment of the risk of recidivism posed by sexual offenders, and the various treatment approaches to sexual offending.

Sexual Offenders

Males commit the majority of sexual offenses. Only a small proportion of all sexual offenses are perpetrated by female offenders, but it is possible that female participation in sexual abuse is underestimated due to commonly accepted gender roles. In addition, a majority of sexual offenders know their victims personally, and most sexual crimes occur in the residence of the offender or the victim.

Notwithstanding these general patterns, sexual offenders are a heterogeneous group. Their age, culture, education level, employment, marital status, and socioeconomic background vary. Their sexual crimes also differ: Some offenders use physical force, others threaten their victims, and

still others use manipulation to gain compliance from their victims. Some crimes involve physical contact with a victim, including kissing, sexual touching, oral sex, and penetration. Other offenses do not involve direct contact, including exhibitionism and trading of child pornography. Some offenders have a small number of victims, while others have many. Some victims are abused once, while others are repeatedly victimized over long periods of time. Therefore, although the term *sexual offender* is commonly used to describe all these perpetrators, there is no such thing as a typical sexual offender. Differences in the range of offenses, the variety of contexts, and offending rates also result in varying levels of risk of future sexual offending. The average sexual recidivism rate over a 5-year follow-up period is 13%, but this rate varies depending on an offender's characteristics.

In order to understand the heterogeneity in sexual offenders, two factors must be considered. First, offenders can be differentiated based on the age of their victims. Sexual offenders who commit their crimes against child victims are classified as child molesters, while those who commit crimes against adult victims are classified as rapists. Rapists and child molesters represent two different profiles of sexual offenders. Rapists are typically younger and are more versatile in their criminal careers, being involved in many crimes that are not sexual in nature. In comparison, child molesters are older when they commit their sexual offenses. They are also more specialized in sexual crimes. In addition, a larger proportion of rapists' sexual crimes involve stranger victims and use of force. Rapists and child molesters are also different in their rates of sexual recidivism.

The second important factor differentiating sexual offenders is the age of the offender. Although a sizeable proportion of all sexual crimes are committed by juveniles, these offenders constitute a group that is distinct from adult sexual offenders. Their sexual crimes are different: They are more likely to involve sexual offenses committed in groups, to occur in schools, and to be perpetrated against male and younger victims. The criminal careers of juveniles are also different. The majority of juvenile sexual offenders do not continue to commit sexual offenses in adulthood once they have been detected. Juvenile offenders have lower

rates of sexual recidivism compared to adult offenders. Therefore, juvenile sexual offenders are not younger versions of adult sexual offenders but a distinct category of offenders.

Etiology

There are multiple explanations for what causes someone to commit a sexual offense. *Biological factors* have been noted in some subgroups of sexual offenders. Offenders who are sexually attracted to children (i.e., pedophiles) generally have abnormalities in their left temporal lobe, have shorter height, are more frequently left-handed, and have lower intelligence levels. Right temporal lobe abnormalities are often found in sexual offenders who commit sadistic sexual offenses. *Cognitive factors* may also play a role in the etiology of sexual offending. Many sexual offenders have cognitive distortions, which are inaccurate beliefs that initiate, facilitate, and justify sexual offenses. Examples of such distortions include the belief that a child victim is not being harmed by the abuse or that an adult victim is partly to blame because of her or his clothing or intoxication. *Social learning factors* specifically examine learning processes about sexual offending. The abused–abuser hypothesis posits that some child victims of sexual abuse will themselves become sexual offenders through learning processes in which they model the same behavior as their abuser later in life. Although many sexual offenders were sexually abused as children, a majority of children who are victims of sexual abuse do not become offenders themselves. Learning can also occur through the use of pornographic materials. Sexually violent pornography—also called *rape pornography*—has been demonstrated to increase hostility toward women and acceptance of rape myths, indicating that some learning processes are at play. The influence of child pornography potentially involves learning processes, considering that some child molesters view child pornography. It should be noted, however, that a causal link between viewing child pornography and committing contact offenses against children has not been established. Finally, *personality factors* investigate the association of specific traits with sexual offending. Antisociality and psychopathic traits are frequently associated with impulsivity, anger, and lack of guilt and empathy. These factors

can influence the development of deviant sexual interests and later manifest in sexual offending.

Etiological models of sexual offending integrate various biological, cognitive, learning, and personality factors to provide explanations for sexual offending. Employing a rigorous methodological approach, the work of Raymond Knight has contributed to the development of etiological models applicable to child molesters and rapists. Two paths were identified to predict sexual offending against children. The first path focused on externalized factors and emerged specifically from experiences of emotional and sexual abuse leading to sexual fantasies about children, cognitive distortions about the abuse of children, and sexual arousal to children. The second path consisted of internalized factors that emerged from the offender's experience of emotional abuse. In the case of sexual offending against adult victims, three etiological components were important: sexualization, impulsivity, and violence. These facets were also found to correlate with sexual offenders having experienced abuse in childhood, which led to impulsivity in behaviors, hypersexuality, and aggressive sexual fantasies.

Classification

Typological studies have commonly distinguished five types of rapists. The *opportunistic* rapist is impulsive and predatory. There is no emotional motivation behind this offender's sexual crimes, but the offender commits rape when situational and contextual factors present an opportunity to do so at low costs. The *vindictive* rapist is motivated by misogynistic anger that is exclusively directed at women. These rapists will often have conflictive relationships with a significant woman in their lives, such as a mother or a wife, and will symbolically get back at this woman by committing rape. In comparison, the *pervasively angry* rapist is angry throughout all aspects of life. This offender's anger is equally oriented at men and women, and conflictive relationships are frequent. The *sexually motivated* rapist is motivated by a desire to obtain sexual gratification. Sexual fantasies play an integral role in the rapes committed by this offender. Finally, the *sadistic* rapist experiences sexual gratification when inflicting pain and humiliation on the victim. Sadistic rapes often

involve degradation, mutilation, and torture of the victim but are generally infrequent.

Child molesters have typically been classified into four categories. The *fixated* or *preferential* child molester is sexually attracted to children. This type of sexual offender will often be diagnosed with pedophilic disorder according to the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition*. Because children constitute the preferred sexual partner for this type of offender, the offender will often actively pursue opportunities to commit sexual abuse against child victims and will often have a high number of victims. In comparison, the *regressed* child molester is not sexually attracted to children but offends against children because they are easily accessible alternatives to age-appropriate partners. Men who sexually abuse their own children may fall into this category. The *exploitative/criminalized* child molester is generally involved in a variety of property and violent crimes throughout the offender's criminal career and impulsively commits sexual assault against a child when presented with an opportunity. Finally, the *aggressive/sadistic* offender is primarily motivated by anger and will execute brutal sexual acts against the sexual victim. The goal of a sadistic child molester is to hurt and humiliate the victim. This is the rarest category of child molester.

Legal Measures

One of the most enduring ideas about sexual offenders is that their behaviors cannot change and that they will continue to commit sexual crimes when released from prison. Public fear of convicted sexual offenders committing new sexual crimes has resulted in a number of legal measures developed specifically to monitor and control them. Civil commitment is a legal procedure allowing the indefinite institutionalization of offenders judged to pose a risk of sexual harm to the community. It has been applied to prevent the release of many sexual offenders at the end of their prison sentence. Instead, offenders are transferred to civil commitment institutions and kept until a court determines that they are unlikely to engage in future sexual offending. The use of ankle monitors is another example of a legal provision specific to sexual offenders. These devices track offenders'

movements using satellite GPS signal. Parole officers can be informed of offenders' movements during their daily routines in real time or can review them at a later time. Registration and notification are other legal measures imposed on sexual offenders at release. Registration refers to a set of procedures that offenders must follow to disclose information concerning their identify and sexual conviction to law enforcement. Multiple countries have implemented registration procedures for sexual offenders, including the United States, Canada, Australia, New Zealand, and the United Kingdom. In comparison, public notification laws refer to the system by which information about registered sex offenders is transmitted to the public. This information includes a recent picture, name, current residential address, and place of employment, along with a description of the sexual offense. This information is typically communicated to the public through the Internet or using announcements in neighborhoods where offenders reside or work. The United States is the only country where information about registered sexual offenders is routinely made available to the public. Additional legal provisions frequently imposed on sexual offenders are residential restrictions and employment restrictions. These measures dictate where a registered sex offender can live and work. Examples include the prohibition to reside within a number of feet of a school or park or to work in settings where children are present. The use of a computer is also prohibited at times for some sexual offenders.

Public safety against sexual harm is often cited to justify many of the legal provisions applicable to sexual offenders. Their effectiveness has been questioned, considering that many of these measures do not reduce sexual recidivism in offenders, although their implementation and enforcement costs are high. In addition, some of these measures create difficult living conditions for sexual offenders and can hinder sexual offenders' reintegration to the community. These measures constitute additional punishment for crimes that are socially condemned and that generate public fear.

Risk Assessment

The issue of assessing risk of sexual recidivism in sexual offenders is important considering the public concern for safety. Multiple approaches measure

the risk posed by sexual offenders. *Unstructured clinical judgment* involves a mental health specialist reviewing the circumstances of a case and making a judgment call about the likelihood of recidivism. This method of assessing risk in sexual offenders has been criticized because of its lack of reliability. A second method involves the utilization of *static actuarial assessment tools* in which an empirically validated instrument is used. An actuarial instrument typically comprises only a small number of items that generate a total risk score that can be translated into a risk category. Previous research has associated each risk category with known sexual, violent, or general recidivism rates in samples of sexual offenders who have been followed over long periods of time. Generally, the people who conduct actuarial risk assessment have received formal training to learn how to code each item reliably. Multiple actuarial risk assessment tools have been developed and used on adult sexual offenders, notably the Rapid Risk Assessment for Sexual Offense Recidivism, Static-99, Sex Offender Risk Appraisal Guide, Minnesota Sex Offender Screening Tool-Revised, and Vermont Assessment of Sex Offender Risk. Actuarial risk assessment tools have been found to yield more reliable results in the prediction of sexual recidivism than unstructured clinical judgment. However, these instruments are criticized because their items are static and unchangeable (e.g., number of offenses, gender of victims). The use of such static factors cannot account for changes in offenders (e.g., aging, treatment) that would reduce their likelihood of sexual recidivism. The communication of the level of risk and its interpretation can also be an issue. The third approach uses *actuarial instruments including both static and dynamic factors*. The assessed level of risk of sexual recidivism therefore accounts for the specific circumstances of offenders, including age, employment status, living conditions, degree of supervision, and cooperation of the offender with supervision. Examples of risk assessment tools that include dynamic factors are the Stable-2007/Acute-2007 and the Structured Risk Assessment-Forensic Version. These newer risk assessment tools do not have the same volume of empirical research backing them as do static actuarial instruments.

Risk assessment tools are used frequently in a variety of settings throughout the criminal justice

system. They are used to determine sexual offenders' sentences; to identify whether an offender should be the target of treatment specific to sexual offending; to determine the length and dosage of this treatment; and to make determinations regarding civil commitment, return to the community, and the imposition of release conditions such as registration, public notification, and residency restrictions.

Treatment

There are successful interventions to treat adult and juvenile sexual offenders, and it is possible for sexual offenders to change their behavior. A reliable approach often used to treat sexual offenders is cognitive behavioral therapy (CBT). As its name implies, CBT focuses its therapeutic intervention on an offender's cognition and behaviors. The cognitive aspect focuses on changing attitudes and feelings (e.g., dysfunctional thinking supportive of sexual offending). The behavioral aspect of CBT focuses on changing patterns of behaviors that are inappropriate (e.g., acting on sexual impulses). Relapse prevention is a common type of treatment that falls into the CBT category. Relapse prevention constitutes a behavioral management strategy aimed at preventing relapse in offenders over the long term by identifying risk factors that increase their likelihood of engaging in sexual offending and then developing coping strategies. It has been established in meta-analytic studies that CBT is effective at preventing sexual recidivism in both adult and juvenile sexual offenders.

A second type of treatment applied to juvenile sexual offenders is multisystemic therapy (MST). MST focuses on the family and community to prevent the perpetuation of a cycle of sexual offending. In addition to working with juvenile offenders, the therapeutic intervention of MST includes their families, schools, and communities. The goal of the intervention is to improve the supervision and disciplining of juvenile offenders and reduce their association with delinquent peers. MST has been shown to reduce recidivism and problematic sexual behaviors in juvenile sexual offenders.

Medical interventions are a third type of treatment for sexual offenders. These medical procedures can be physical or chemical in nature. Physical procedures include the removal of testicles in mechanical castration surgery. This

procedure is irreversible. Chemical castration is a reversible alternative that involves hormonal therapy in which testosterone levels are lowered. Both physical and chemical interventions are aimed at the reduction of sexual drive in men who have committed sexual offenses. Only a small number of studies have investigated the effectiveness of this type of treatment on recidivism of sexual offenders and their results are inconclusive. In addition, there are important ethical considerations to these procedures. Some medical professionals consider such treatment to be punishment and are reluctant to administer it. These medical procedures call into question the respect of sexual offenders' basic human rights.

The role of community intervention in the treatment of sexual offenders is promising. An example is the development of Circles of Support and Accountability. In Circles of Support and Accountability, a sexual offender who is released into the community is supported by an outer and an inner circle of people with the aim of preventing sexual recidivism. Members of the outer circle are professionals typically involved with sexual offenders at their release from prison, including parole or probation officers and mental health professionals. They work with members of the inner circle, who are trained volunteers from the community. These members support the offender through weekly conversations and ensure that the offender is able to find a residence and employment and to access other social services. Although not yet the object of methodologically strict evaluations, Circles of Support and Accountability appear to reduce sexual recidivism in participants.

SEXUAL OFFENDERS, PUBLIC PERCEPTION OF

Sexual offending results in drastic negative consequences for victims and their families. The nature of this offending behavior results in very strong public reactions and opinions about this subgroup of offenders. It is important to consider public perceptions or attitudes, particularly in the context of community reintegration of sexual offenders. Attitudes are an expression of favor or disfavor toward a particular entity and formed as a result of both direct and indirect experiences. Public attitudes inform and impact policy development, reintegration approaches, and community-based

support for sex offenders. It is essential to understand public attitudes toward sex offenders because attitudes are linked to behavior, and as a result, the public's responses to this group in the community may limit an offender's ability to successfully reintegrate and refrain from reoffending. This entry addresses public perceptions regarding sex offenders, specifically examining beliefs, feelings, impressions, attitudes, stereotypes, and views about adult male sex offenders, who make up the majority of convicted sex offenders.

Media Influence

Many members of the public do not directly interact with sex offenders, and in the absence of direct contact, public attitudes are influenced by depictions of sex offenders in the media. Researchers in the United States, United Kingdom, and New Zealand have found that the majority (between 74% and 90%) of the general public report that they obtain information related to sex offenders from media outlets, and only a minority access official crime statistics to learn about this group. Beyond the lay public, even U.S. legislators involved in creating sex offender policy have indicated that they receive a portion of the information that informs their legislative decisions from news accounts. In light of this reliance upon the media for information about sex offenders, it is worth considering the nature and quality of this information.

Media focus is primarily on high-profile, heinous violent sexual offenses that are repeatedly and extensively covered. These events are emotionally charged and tend to elicit panic and fear. Compared to other violent crimes discussed on TV news, sexual crimes are also more likely to be presented in a fear context. Persistent focus on these horrific events, which in fact occur relatively infrequently, contributes to the public's panic and indignation toward sex offenders.

The media also contributes an inaccurate representation of sexual offenders and perpetuates erroneous information about them. In one U.S. study completed in 2012, researchers found that sex offender myths were presented in about one third of randomly selected U.S. newspaper articles. Myths included that sex offenders have high recidivism rates, are a homogenous group, and do

not respond to treatment. Myths were also present even while discussing the effectiveness of particular sex offender policies.

Media portrayals of sex offenders are also perceived as negatively impacting a sex offender's ability to successfully reintegrate into the community. One 2012 Canadian study found that media portrayals were perceived as detrimental to an offender's ability to find employment and stable housing and to make positive relationships, all of which are factors related to recidivism.

With this in mind, it is reasonable to assume that media portrayals have influenced public attitudes toward sex offenders and have perpetuated stereotypes and erroneous beliefs the public holds.

Public Feelings and Perceptions

Sex offenders are highly stigmatized, and public feelings toward this group are more negative than toward other types of offenders. Generally, the public detests all offenders of sexual crimes, and in particular, more negative feelings are reported toward contact child sex offenders. The public also reports a high amount of fear of convicted sex offenders, fear that varies by type of sexual crime. For example, one U.S.-based study found that pedophiles and incest offenders were the most feared, while the offenders convicted of statutory rape (i.e., sexual intercourse with someone below legal consent age) were the least feared.

Generally, results from North America, the United Kingdom, Australia, and New Zealand indicate that the public collectively views sex offenders as being at high risk to reoffend, often overestimating recidivism rates by 3–5 times. The public also believes sex offenders are generally resistant to treatment and therefore cannot be rehabilitated. Other commonly endorsed myths found across several studies were the general myth of homogeneity of this group (i.e., all sex offenders are more similar than different, and there is little variation among this offending group); that the majority of sex offenders were abused as children; that half of sex offenders are seriously mentally ill; and that sex offenders tend to use aggression and force when committing a sexual offense. Finally, researchers have found that the public generally tends to overestimate the number of offenders who are strangers to their victims, or

fear *stranger danger*. Interestingly, one U.S. study conducted in 2009 found that respondents who reported knowledge of a local neighborhood sex offender (obtained through public sex offender registries) were more apt to endorse the stranger danger belief.

Attitudes About Sex Offender Policy

Beyond these general beliefs about sex offenders, public attitudes related to different sex offender policies have also been researched. Generally speaking, research conducted in the United States suggests that the public has high levels of support for management policies that provide added restrictions, monitoring, and sentencing/incarceration for sex offenders. These policies include community notification, GPS/electronic monitoring, and residence restrictions. The public also believes that these policies are effective in reducing recidivism, despite evidence to the contrary. Notably, several studies have shown that the public would support these policies even without evidence they reduce offending behavior. Further, many citizens in one 2011 U.S. study indicated they were aware of their state's sex offender registry; however, the majority (60%) reported they had never accessed it because they had no interest in the information. The public also has differential levels of policy support based on offender types; for example, higher rates of support for offender registration were found for offenses involving child victims, in contrast with offenses involving spousal rape.

Although the term *sex offender* is intended as a neutral descriptor, the term itself is laden with negative connotations and stereotypical beliefs and has been found to impact one's level of support for particular policies. Researchers in 2015 investigated the impact of the label *sex offender* and found that when this label was used, rather than more neutral phrasing, responders were more certain in their support for various restrictive management policies (i.e., the label increased attitude certainty).

Importantly, the public's perceptions of sex offenders and sex offender management are complex and not uniform. For example, one U.K. study from 2008 found that the public identified treatment and rehabilitation as being prime objectives of incarceration, alongside punishment

and public safety. The public was also in support of sex offenders receiving additional support on release and indicated a tolerance, to a certain extent, of offender resettlement in the community.

Demographic Differences

The relationship between attitudes toward sex offenders and particular demographic variables has been investigated, with mixed findings. Variables typically studied include age, gender, educational level, political orientation, parental status, marital status, and level of contact with sex offenders.

Some studies have found differences related to certain variables such as gender and education, while others have not. For example, several studies have found significant differences among genders. Females generally report more punitive and negative attitudes and estimate higher rates of recidivism for sex offenders compared to males; however, these are not universal findings. In several studies, higher educational levels have also been associated with more rehabilitative/positive attitudes toward sex offenders. More rehabilitative attitudes have also been linked with younger age, more liberal political orientation, and having no children, although these patterns are not consistently observed. A few North American studies have found that ethnicity or minority status was associated with more negative attitudes toward sex offenders and less belief in rehabilitation. Findings related to marital status have been inconsistent.

In general, increased contact with offenders is associated with less negative attitudes, although variation exists depending on the nature of the relationship or interaction. Persons with more contact with sex offenders in a treatment setting, or who have specialized education, have more positive attitudes toward sex offenders when compared to students and general community members. There is less certainty when it comes to the impact of victimization on attitudes. Several studies that surveyed persons with personal experience or who are close to a victim of sexual violence found that this factor had no influence on general attitudes toward sexual offenders and the endorsement of myths toward this offending group. In

contrast, other studies have found that former victims or persons who are close to a victim or perpetrator of sexual violence had less negative attitudes toward this group and endorsed fewer misperceptions about them. The relationship between demographic variables and attitudes is complex and requires further study.

Modifying Attitudes

Some evidence suggests that attitudes toward sex offenders can change as a result of training and/or education; however, the findings are not conclusive, and more research is required in this area. Several studies conducted in the mid-1990s and early 2000s in the United States and United Kingdom suggested that shortly following training regarding sex offenders, the public and professionals who work with this population had significantly more positive attitudes. In 2012 and 2014, American and New Zealand researchers found that following a brief psychoeducational intervention via a discussion group, attitudes toward treatment of sex offenders in a student sample improved significantly. When students were presented with informative media portrayals of sex offenders (vs. typical media portrayals as discussed earlier), there was a significant improvement in their beliefs about sex offenders. For example, after reading an informative media story about sex offenders, student participants were less likely to endorse particular myths about sex offenders and less likely to overestimate their rates of recidivism.

Other researchers have been unsuccessful in altering attitudes. A 2010 review of the limited research on attitude change toward sex offenders suggested that brief educational programs might be ineffective at changing the attitudes of professionals working with sex offenders, including those of prison employees and police officers. Although there is some evidence for short-term change in attitudes, it is unclear if these changes will have long-term impact.

Generally, researchers have observed that feelings (i.e., the affective component of attitudes) are more ingrained and thus less amenable to change. Providing educational information can be influential in changing attitudes toward sex offenders, and an emphasis on the cognitive aspect, including

stereotypical thoughts about this group (e.g., they are at very high risk to reoffend, they cannot be treated), is an important target to focus on.

“Not In My Backyard” Phenomenon

A final noteworthy factor when considering attitudes toward sex offenders and sex offender management policies is the “not in my backyard” phenomenon. This can refer to an aversion to directly interacting with sex offenders; it may also refer to the idea that while many may endorse positive attitudes toward sex offenders and rehabilitation, these attitudes may not translate into behavior. For example, although someone may recognize a need for and support sex offender rehabilitation and reentry broadly speaking, when asked specifically, this individual would not support a community-based treatment facility being built in his or her own neighborhood. This suggests there is a divide between attitudes on a proximal/personal level and policy level, which has implications for successful offender reintegration.

The limited but growing research related to perceptions of sex offenders and the resulting wide-ranging practical implications have provided a great deal of information; nevertheless, more research is required.

SEXUAL OFFENDERS: TREATMENT APPROACHES

The main objective of this entry is to examine whether there is a particular style of treatment that delivers maximal outcome in terms of reducing sexual reoffending. For example, examination of the efficacy of evaluated sexual offender treatment programs may suggest superiority of a certain method of treatment, such as cognitive behavioral therapy (CBT), and for treatment approach, such as the therapist's style. This entry focuses on the treatment of adult male sexual offenders, as they constitute the highest proportion of sexual offenders.

Approaches to Treatment

Early approaches to treating sexual offenders emphasized behavioral and psychodynamic orientations; however, few of these approaches were

empirically examined or provided convincing evidence for their efficacy. Due to a growing realization of the limitations of behavioral treatment for sex offenders, in the 1970s, behaviorally based programs started to incorporate cognitive elements into treatment, such as distorted cognitions, empathy, and social skills training.

In the 1980s, relapse prevention (RP) strategies, which had been used with some degree of success with substance abusers, started to be incorporated into sexual offender treatment. Due to its face validity and intuitive appeal, but not in response to evidence, RP was rapidly adopted by almost all CBT programs for sex offenders in North America. The RP approach was eventually strongly criticized in a series of papers by Tony Ward and his colleagues, and William L. Marshall and Dana Anderson later demonstrated that there was no convincing evidence that the RP approach enhanced the effectiveness of cognitive behavioral treatment. In what should perhaps have been the death knell for the RP approach, a large-scale randomized controlled trial implemented at a California state hospital failed to demonstrate any benefits of an RP program. However, likely due to its appeal to therapists and case managers, the RP approach persists in a significant percentage (>66%) of current sex offender treatment programs for adult males in both community and institutional settings.

As a result of changes in theories of sexual offending, research on offenders in general, studies examining the features of effective therapists and groups for sex offenders, and large-scale meta-analyses identifying a broad range of dynamic risk of reoffending targets in sex offenders, current treatment approaches target a comprehensive range of issues. Typically included in treatment for sex offenders are procedures aimed at changing distorted cognitions, enhancing empathy, increasing self-esteem, equipping offenders with better coping skills, providing offenders with knowledge about healthy sexual functioning and about the features and benefits of enhanced intimacy, and reducing deviant sexual interests while increasing sexual arousal to adult consenting sex. However, some of these comprehensive programs appear to be more effective than others.

Based on a growing accumulation of empirical evidence, researchers can now say that treatment

to reduce sex offenders' risk of reoffending can work. They can also say what does not work. Some of the things done with the intention of reducing recidivism, which are now known not to be effective, include the following: only targeting deviance, addressing issues that have not been demonstrated to be related to reoffending (i.e., targets not relevant to risk, such as denial or victim empathy), removing sex offenders from treatment prior to completion, the therapist being either aggressively confrontational or unchallenging, employing only avoidance strategies, overtreating, and using punishment or shaming as a treatment strategy. In terms of the things that do work, perhaps the most important model of effective offender treatment, which has also been empirically validated for use with sex offenders, is Donald Andrews and James Bonta's Risk-Need-Responsivity model.

The Risk principle accounts for the smallest amount of the beneficial changes induced by treatment, but that should not be taken to mean it is not important. This principle indicates that the greatest benefits (i.e., reductions in recidivism) will be obtained by directing treatment at the highest risk offenders. Where resources are limited, only the highest risk offenders should be treated; when greater resources are available, the most extensive and intensive program should be reserved for the highest risk offenders with less time and energy directed at the moderate-risk and lower risk clients.

The Need principle requires treatment to focus on the modification of criminogenic factors; that is, those features of clients that have been shown to predict reoffending but are at least potentially changeable. This principle, when properly applied, accounts for a significant amount of the variance in changes induced by treatment. The criminogenic needs that have been identified in sex offenders are well described in a paper by Ruth Mann and her colleagues across four domains: (1) sexual factors, such as deviance and sexual preoccupation; (2) relationship problems, such as intimacy and attachment problems; (3) cognitive factors, such as attitudes and a lack of empathy; and (4) self-regulation problems, in particular emotional dysregulation.

The Responsivity principle has two components—general and specific—which reflect the

way in which treatment is delivered. Specific responsivity requires therapists to adjust their approach to the unique features of each client: both enduring features (e.g., cultural characteristics, intellectual level, personality style) as well as day-to-day fluctuations in mood and motivation. The general responsivity principle, however, may exert the greatest beneficial changes, the core elements of which include the need for therapists to display the traditionally established features of warmth, empathy, respect, and support while modeling and reinforcing prosocial attitudes and behaviors. When properly enacted, the Responsivity principle can, on its own, generate effect sizes amounting to a 20% reduction or greater in recidivism.

Subsequent research on process factors (i.e., the features of treatment delivery) in sex offender treatment support and extend Andrews and Bonta's observations. In detailed studies of sex offender treatment in English prisons, Marshall and his colleagues demonstrated that treatment was maximally effective when therapists displayed warmth and empathy, were rewarding of clients for steps in the desired direction, and provided guidance as needed, what they called *directiveness*. The presence of these therapist features explained between 30% and 60% of the changes brought about by treatment. The benefits of these characteristics of effective therapists had been demonstrated quite clearly in the general therapeutic literature over many years. In addition, Martin Drapeau and colleagues found that sex offenders reported the behavior of their therapists to be the crucially effective element of their treatment. The behaviors these offenders pointed to as critical were just those that Marshall's studies had shown to produce effective outcomes.

Recent Innovations

There are a number of recent theoretical approaches to the treatment of sexual offenders that have received some attention. Contrary to the classic RP model, evidence from other areas of psychological research has shown that avoidance goals are rarely maintained, whereas approach goals are typically sustained over time. That is, adopting a positive approach to psychological treatment and focusing on recognizing and

building clients' strengths is more effective than the traditional way of highlighting and eliminating deficits. Treatment for sex offenders has begun to assimilate these newer, more positively oriented ways of addressing the needs of these clients by adopting Ward's Good Lives Model (GLM) and by integrating the motivational strategies of William Miller and Stephen Rollnick into the treatment of sex offenders.

The GLM arose initially from work in the 1960s, specifically Abraham Maslow's theory that all humans, whether they are aware of it or not, strive for self-actualization (i.e., the realization of their inner potential). These ideas are embodied in the field of positive psychology. Ward has integrated these developments into the GLM, which he suggests provides an approach to the treatment of sex offenders complementary to Andrews and Bonta's Risk-Need-Responsivity model. The GLM outlines areas of functioning in which people attempt to maximize satisfaction across their life span. Most of these areas (e.g., satisfactory intimate relations, healthy sexuality) map well onto the factors that have been shown to be criminogenic deficits among sex offenders. The GLM lends itself well to a strengths-based approach emphasizing development of capacities to overcome deficits and offers sex offenders a hopeful way of looking at their problems.

The motivational interviewing (MI) approach advocated by Miller and Rollnick in the early 1990s also fits well with a strengths-based approach to the treatment of sexual offenders. In their view, the essential features of the spirit of MI involve (a) collaboration between therapist and client, (b) evocation from the client of insight and reality, and (c) autonomy where the focus is on the client being responsible for change. In addition, Miller and Rollnick describe four guiding MI principles for therapists to follow: (1) expressions of empathy by responding to the client's perspectives as understandable and valid, (2) discrepancy between the client's present situation (including his or her attitudes and behaviors) and the client's goals, (3) rolling with the resistance that clients typically have toward change, and (4) supporting and encouraging the client's emerging self-efficacy. Other researchers have described the application of MI

to the treatment of sex offenders, pointing to evidence indicating that a lack of motivation is the primary reason for offenders dropping out of treatment.

An Integrated Strengths-Based Treatment Program

Provided here is a brief summary of the strengths-based approach to treating sexual offenders (a comprehensive description of the program can be found in the 2011 book *Rehabilitating Sexual Offenders: A Strength-Based Approach* by W. L. Marshall and colleagues). Treatment is presented to clients in three phases: Phase 1 is aimed at motivating and engaging clients, Phase 2 directs efforts at overcoming criminogenic needs by providing clients with the skills required to meet their needs in prosocial ways, and Phase 3 integrates what the offenders have learned into a future-oriented set of self-management plans consistent with the areas identified in the GLM. One problem with most sex offender programs, and indeed with CBT more generally, is a failure to instill in clients the idea that treatment simply moves them along a path toward attaining a better life and that they must continue to develop after discharge; the GLM provides a model that encourages a life course striving toward greater fulfillment. Within the context of a CBT orientation focusing on building an effective therapeutic alliance with the client, therapists in the program are trained to exercise being warm, empathic, rewarding, and directive and to create an effective group climate characterized by expressiveness and cohesion.

Outcome evaluations of this approach suggest it is effective. For example, Marshall and colleagues followed 535 sex offenders who participated in the treatment program in the federal correctional service over an average follow-up of more than 5 years and, subsequently, more than 8 years and observed low rates of reoffending based on reconviction and new charges data from the nationwide Royal Canadian Mounted Police database, 3.2% and 5.6%, respectively, versus the expected rate of reconviction based on actuarial estimates of 16.8% and 23.8%, respectively. The researchers have also compared their findings with two other groups matched for risk, namely, a

treatment as usual sex offender program ($n = 625$) and an untreated group ($n = 107$) of sex offenders from the same prison system (i.e., the Correctional Service of Canada). In this study, the treatment group was found to have statistically significantly lower recidivism rates and higher treatment effect size than either of the two other groups—that is, the program versus treatment as usual sex offender program ($n = 1,204$; 50% reduction in the odds of reoffending) and the program versus untreated ($n = 686$; 65% reduction in the odds of reoffending). These results provide encouragement that the program addresses the right criminogenic need issues in the right way.

Final Thoughts

The crucial features of effective treatment for sexual offenders appear to be (a) matching treatment dosage to actuarially determined risk, (b) primarily addressing targets that have been shown to predict reoffending (i.e., criminogenic); (c) delivering treatment in ways that motivate and engage the client, and (d) using effective procedures to achieve change on the targets of treatment. Treatment programs for sexual offenders that integrate these elements can demonstrate significant reductions in reoffending, thereby keeping society safer by reducing potential future victimization.

SEXUAL OFFENDERS: TREATMENT OUTCOME RESEARCH

The impact of sexual violence is far-reaching, for the victims, the offenders, and the families of both. Thus, the effective treatment of sexual offenders is one of the key objectives of the criminal justice system. Effective treatment will ensure the prevention of future victims and can help the offenders move forward to meaningful lives in which no one else is harmed. This highlights the need to conduct quality treatment outcome research. Treatment effectiveness research commonly involves comparing the recidivism rates of those who received treatment to those who did not. As noted in this entry, the details of these comparisons require careful attention. A number of methodological considerations in conducting treatment outcome research are outlined along with discussion of the pros and cons of various evaluation designs, followed by what treatment evaluations reveal about to what extent sex offender treatment *works* for reducing sexual reoffending.

Outcome Research Considerations

A number of important decisions must be made in designing a treatment outcome evaluation. These include comparison groups, defining *reoffending*, base rates, treatment characteristics, and offender characteristics.

Comparison Groups

Perhaps one of the most important aspects of designing an evaluation is determining which groups will be used to compare the effects of treatment and no treatment. These should be groups that do not differ from each other in any systematic way, so that ideally the only thing that differs between them is whether they attended treatment or not. This is not as straightforward as it seems. There are ethical reasons for attempting to treat every sex offender who is willing to

attend treatment (e.g., if treatment works to reduce reoffending, we need to try to ensure every offender gets treatment to prevent future victims), but there are also methodological reasons for withholding treatment from some offenders, even if they are willing to attend (e.g., we cannot say treatment works without well-designed studies comparing, otherwise equal, treated and untreated groups).

It is also important to note that research has shown that those who refuse or drop out of treatment tend to have higher recidivism rates than those who are willing to attend treatment, so attention must be given to how to handle these types of cases in terms of possible inclusion in comparison groups. Including them in a *no-treatment* group could increase the group's risk level, making it less likely that differences between treatment and comparison groups could be attributed solely to the impact of treatment. An intent-to-treat design is often used; in this design, dropouts and refusers are included in the treatment group since they *intended* to attend sex offender treatment, even though they did not complete it.

Defining Reoffending

One of the key outcomes examined in sex offender treatment research is a reduction in reoffending, thus there is a need to be explicit about what is meant by *reoffending*. It is most commonly assessed as any new criminal convictions for sexual offenses, but other common outcomes are other violent offenses (including sexual and nonsexual), nonviolent offenses, or even any new convictions in general. Some also choose to include charges as well as convictions or include records of any time the offender comes to the attention of the police. Using convictions increases the confidence that the new offense occurred but results in lower rates because the criteria are more stringent. Some researchers argue that it is acceptable to use charges because there must have been enough evidence to support filing a charge. Also, charges may be dropped for a number of reasons (e.g., lack of evidence strong enough to result in a conviction), so it is possible an offense occurred even without a conviction.

Base Rates

The criteria used to define reoffending influence the base rate of offending (i.e., the rate of reoffending in the sex offender population). This rate will vary depending on whether one is using charges or convictions and the specific type of convictions. Sex offending is relatively infrequent (approximately 10–15% over 5 years). Although this infrequency is a positive for society as it means fewer new victims, it makes using recidivism as an outcome challenging because it involves examining associations with a low-frequency event. For instance, if 10% of sex offenders reoffend, it becomes difficult to see reductions in offending from treatment since there is little room for a reduction in offending to be observed (e.g., compared to 50% which has more room to move). The base rate is also subject to fluctuations due to a number of different factors such as jurisdictional differences in reporting of offenses, laws and policies related to sex offending, and how long the offenders are followed up in the community (e.g., a 2-year follow-up allows less time for a new offense to occur and will result in lower recidivism rates compared to 10 years). Thus, better designed studies employ longer follow-ups.

Treatment Characteristics

A crucial consideration in determining whether sex offender treatment works is the type of treatment examined. Treatment can vary quite considerably from pharmacological, purely behavioral, or cognitive behavioral approaches to those that are more eclectic or insight oriented. Examining older treatment approaches allows for more time to pass for reoffense data to accumulate, which also strengthens statistical analyses. Many of the older approaches, however, do not represent current treatment practice, so they would not provide an accurate illustration of whether current treatment approaches work. Other treatment considerations include the intensity of the treatment being offered (e.g., once a month for 6 months, twice a week for 2 years), the foci of treatment (e.g., targeting risk factors linked to sexual offending), how treatment is delivered (e.g., if flexibly tailored to the unique needs of the offender), and the setting (e.g., whether the treatment was offered in prison or the community). Thus, better designed

studies focus on current treatment practices with these characteristics.

Offender Characteristics

Finally, it is also possible that some types of offenders respond differently to treatment than others (e.g., those with child victims may respond better to certain types of treatment than those with adult victims) or that they possess risk factors that influence their risk of reoffending (e.g., younger offenders have higher rates of reoffending than older offenders). Thus, better designed studies account for these offender characteristics.

Treatment Outcome Evaluation Designs

Once thought has been given to the considerations outlined in the previous section, treatment outcome evaluation design can be decided. The strengths and weaknesses of each are reviewed here.

Descriptive

One outcome approach is simply to report the recidivism rate for that particular program. If this rate is low, it could be suggested that this is an indication that treatment is having an impact on reoffense rates. However, without a comparison group, it is not possible to attribute the reoffense rate to treatment because any number of the methodological factors reviewed could be contributing to this.

Randomized Controlled Trials (RCTs)

RCTs are often noted to be the gold standard of evaluation designs. These take all willing offenders and randomly allocate them to a treatment or control group to ensure that there are no systematic differences between the groups. Differences in the characteristics of the two groups should only vary by chance and thus are not meaningful. If there can be confidence that the groups start out equal, any differences later observed between the groups can be attributed to treatment.

However, problems have been noted with RCTs, including the ethical issue mentioned previously. Withholding treatment from willing recipients just to release them and see whether they reoffend may place the public at an avoidable risk; this has been

countered with the argument that if it is unknown if an intervention is effective, then it is not unethical to withhold that treatment from willing participants. Even with random assignment, other unforeseen issues may arise, such as treatment dropout, which poses a threat to the validity of the study as the groups would no longer be equivalent aside from their treatment attendance. Finally, these studies can also be quite expensive to implement. Unless a well-designed study can be conducted with the methodological rigor of an RCT, firm conclusions about whether treatment *works* cannot be drawn.

Matched Comparison

Matched comparison group designs compare those who are treated and not treated by controlling for characteristics of members of each group to try to ensure their equivalence. These have also been referred to as quasi-experimental designs. Groups are matched on characteristics that are expected to have a relationship with recidivism such as the offenders' age, risk level, and victim characteristics (e.g., gender, relationship). By matching these characteristics between the treated and control groups, the understanding is that the most important characteristics are controlled for and that any subsequent differences observed between the groups could be attributed to treatment. Even with such controls in place, there may still be threats to the validity of the study, as other important variables that influence recidivism rates, aside from treatment, may not have been controlled.

Risk Band Analyses

This approach uses the recidivism rates per risk category observed for treated offenders to determine how these rates compare to the published recidivism rates predicted for those risk categories. If the rates observed for the treated group are lower than predicted, one could argue that treatment has had an impact on their recidivism rates. This approach is strengthened if risk bands of treated offenders are compared to the risk bands of offenders known to have not received treatment. However, because the characteristics of the comparison group are not usually known (e.g., if they have been treated or if there are differences in base rates depending on different jurisdictions

where the comparison group data were collected), this poses a threat to the validity of the study. This means that differences in recidivism rates cannot necessarily be attributed to treatment.

Incidental Cohort

Incidental cohort designs compare treated offenders with a comparison group of offenders who did not receive treatment for reasons that are not expected to be related to risk level. This could include comparing the treatment group to a group who attended a different type of program in the past or were under supervision prior to the implementation of treatment, or to a group who were willing to attend but could not be offered treatment for reasons such as lack of resources or living too far a distance from the treatment program. However, one could argue that with historical samples, there could be cohort effects such that the rate of sexual conviction may have changed over time (which may confound group differences possibly attributable to treatment). There may also be other unmonitored differences between the treated and comparison groups in other characteristics related to risk (e.g., motivation), which may pose a threat to the validity of the study.

Statistical Control

Other researchers attempt to statistically control for risk-relevant differences between the groups such as age, offense history, and other offender and victim demographics. Even outcome studies that statistically control for risk can have threats to validity, however. For instance, there may still be important uncontrolled risk-related variables that vary systematically between the groups that can influence outcome.

Does Sex Offender Treatment Work?

There have been several systematic reviews and meta-analyses collating the results of sex offender treatment outcome studies in an effort to answer the question of whether treatment works to reduce reoffending. The results of these reviews have differed depending on the stringency of criteria for methodological rigor the researchers believe is required for the studies they include in their analyses. Applying a study evaluation criteria that only

allows for studies of the highest quality, representing a low to moderate risk of bias (e.g., those using random assignment), some researchers such as Niklas Långström and colleagues concluded that the evidence is weak for the effectiveness of treatment in reducing recidivism. Others have argued that valuable information can still be taken from less than optimal designs. One example of such a meta-analysis is by Martin Schmucker and Friedrich Lösel. They utilized study quality criteria but allowed for the inclusion of studies of lower quality than those included by Långström and colleagues. These more inclusive reviews tend to find an overall positive effect of treatment in reducing sexual recidivism, and in particular, they find stronger treatment effects for medical (e.g., physical or chemical castration) and cognitive behavioral approaches compared to eclectic or insight-oriented approaches. Others such as Robert Karl Hanson and colleagues attained similar findings after screening out studies they felt posed an intolerable risk of bias. Thus, even when the quality of the included studies is considered, these treatment effects remain significant and positive, amounting to a one quarter to one third reduction in sexual recidivism for treated individuals.

Regardless of the stance one takes on the “Does treatment work?” debate, it is important that every effort be taken to evaluate the impact of these treatment efforts. Taking into account the considerations outlined here and selecting an evaluation approach that minimizes biases as much as possible (yet enabling the provision of ethical practice) can go a long way toward definitively answering this question in the future.

SEXUAL OFFENDING

Although sexual offending sounds like a very specific category of illegal behavior, the types of crimes that encompass a sexual element are quite vast and victimize a wide variety of people. Based on the attention given to sexual offenses, especially in the media, one may assume that sex crimes are on the rise. In actuality, however, it is a more complicated issue that takes into account the empowerment of victims to report their victimization, better detection by law enforcement, and the availability of treatment services for offenders. The numbers of sexual crimes have not increased; rather, society has become more attuned to the severe, tragic cases presented by the media and the entertainment industry. Individuals have been sexually victimizing other people, be it adult or child, for as long as human behavior has been studied. The focus of this entry is on the various types of sexual offenses as well as the motivations and risk factors for sexual offending.

Types of Sexual Offenses

Sexual offenses are generally broken down into the following categories: offenses against adults, offenses against children, noncontact offenses, and Internet-facilitated offenses. This allows researchers, investigators, and treatment providers

to focus on motivations and risk factors specific to each category.

Rape is one of the most severe forms of sexual offending that can victimize an adult, causing life-long trauma and impacting a number of indirect victims. In most jurisdictions, rape is generally defined by sexual intercourse (usually involving some form of penetration) that involves force or violence of a nonconsenting partner. However, rape does not always need to consist of force or violence. It can also be considered rape if the victim is unable to give consent for any reason. An adult engaging in sexual activity with someone under the legal age of consent, even if they are similar in age or are agreeing to the activity, is often referred to as *statutory rape*. Individuals who cannot legally consent to sexual activity include children under the specific jurisdiction's legal age limit, intoxicated or incapacitated individuals, developmentally or intellectually delayed individuals, as well as animals in most states.

Other types of sexual offenses against adults can include sexual assaults, sexual battery, forced oral copulation, digital penetration with a foreign object, and spousal rape. The majority of male rapists can be described as antisocial individuals who are criminally minded and who possess the attributes of entitlement and hostility toward women. Sexual recidivism rates (i.e., committing the same sexual offense again) among rapists are fairly low, and they are more likely to commit a different type of violent, nonsexual offense in the future (e.g., assault) rather than another sexual offense.

Individuals who commit sexual offenses against children are generally referred to as *child molesters*. The terms *child molester* and *pedophile* are often and incorrectly used interchangeably. Pedophilic disorder is a clinical diagnosis given to individuals who are primarily sexually attracted to prepubescent children. Individuals who fit the criteria may be attracted to only males, only females, or both male and female children. In addition, they may have a sexual interest in adults. Not all individuals with pedophilic disorder act on their urges and may go their entire lives without molesting a child. Conversely, the majority of individuals who have molested a child would not fit the clinical diagnosis for pedophilic disorder. One incident of child molestation is not, by itself, indicative of a deviant sexual interest.

Most child molestation cases are crimes of opportunity with a victim who is known to the offender. The established relationship, whether caregiver, relative, or teacher, lends to the already trusting nature of the child. Generally, the offender is experiencing a number of contributing risk factors that impair his or her decision to act out sexually with an easily accessible victim—a child in the case of the child molester. However, there are child molesters who may in fact be pedophilic, spending much time and energy into planning their offenses and getting close to large numbers of potential child victims. These individuals are often manipulative and socially savvy, with abilities to persuade parents to trust them in positions of authority over their children. Offenses against children take on many legal titles: continuous child sexual abuse, lewd acts with a child, child molestation, and child annoying. In most jurisdictions, penal code sections will be specific to various age categories of the victim and/or the age difference between offender and victim in order to demonstrate the vulnerability of the child.

Regardless of the type of offense (rape or child molestation), the majority of offenders are male and know their victims prior to the offending behavior.

Individuals who commit noncontact sexual offenses are driven by sexual preoccupation and a compulsion to engage in the behavior. Sexual preoccupation refers to being both psychologically consumed with thoughts about sex and spending large amounts of time engaging in sexual behaviors such as masturbation, pornography consumption, seeking anonymous sex, or visiting strip clubs or massage parlors. Compulsions refer to repetitive behaviors or mental acts that the individual feels he or she *needs* to perform in order to relieve or avoid intense internal distress. These atypical sexual behaviors can include exhibitionism, public masturbation, voyeurism, and obscene phone calls. In each of these cases, the victim is not consenting or is surprised by the sexual behavior. Individuals who engage in exhibitionistic activities typically have adult female victims, but a wide variety of unintended victims may be impacted if the location of the offense is well populated.

The fastest growing area of sexual offending is those crimes that are facilitated by the Internet.

Offenders are using the latest technology to make it easier to commit age-old offenses in the new era. In 2018, the most common types of Internet-facilitated sexual offenses are those having to do with child pornography, solicitation of minors, cyber exhibitionism, cyber voyeurism, and webcam child sex tourism. In the United States, Internet-facilitated sexual offenses were first investigated by federal law enforcement entities. The wide-open Internet was problematic in terms of jurisdiction; therefore, most cases defaulted to federal investigators who had the resources to investigate crimes that had offenders in one state and victims in another. However, local law enforcement agencies are now gaining experience in Internet-driven investigations and are beginning to prosecute such cases.

In terms of child pornography cases, the most common charges involve possession, production, distribution, receipt, and advertisement of child sexual abuse images. When an individual downloads or obtains images or videos of child sexual abuse, the individual is considered to be in possession of the material. Offenders who document the abuse, taking the pictures or shooting the video, are termed *producers*. This can also encompass rings or groups of people who profit from the production by hosting websites or other means of making the material available to the masses. Distribution can be performed in an active fashion such as e-mailing images to another individual, or it can be performed passively by uploading the material to an open server where other people can then download it.

Solicitation offenses facilitated by the Internet are most commonly directed toward luring children to meet up in person. This is not to say that some individuals do not lure adults via the Internet to commit other offenses such as robbery, assault, or rape. The point of contact at the beginning of an online solicitation or enticement usually takes place in a chat room or on a social networking page. Contact can also be made initially via e-mail or on a special interest forum or listserv. The behavior of developing a relationship online mimics grooming techniques that are performed by child molesters in real-life contact offenses. The interaction will generally consist of light conversation about common interests, family and friends, or problems and then leads to information gathering and eventually

sexual questions or comments. The perpetrator may encourage the child to communicate via phone in order to build trust. The intention of these efforts is to establish rapport, gain trust, increase dependency, and eventually to meet in person for sexual activity.

Offenses that take place via the Internet that include the use of webcams are also on the rise. Cyber exhibitionism is committed when an offender exposes his or her genitals to a nonconsenting person by using his or her own webcam. Cyber voyeurism generally occurs when an adult perpetrator instructs a child to undress via webcam or to perform other acts such as masturbation in front of the camera. Some cyber voyeurism offenders may be able to set up cameras or activate victims' webcams and view them without their consent as they are getting dressed or engaging in sexual activity. The victims in these cases can be adults or children. Alternatively, webcam sex tourism is a more specific type of webcam voyeurism where children in developing countries are targeted to perform sexual acts in front of their webcams. There have been some reports of families being paid to have children provide these services to an administrator who maintains such platforms via the Internet. Law enforcement and private investigation agencies are now using computer-generated imagery to lure offenders with a lifelike animated child who can interact with perpetrators while information is being collected on the offender's computer.

Motivations and Risk Factors for Sex Offending

Motivations for the first-time offender vary greatly. Motives can include anger, revenge, sexual arousal, or deviant sexual interests. If a first-time offender is assessed for future risk, it is unknown whether they have prior offenses unless they admit to them. Without prior offenses being connected to perpetrators, it is not possible to truly know how many offenses they have committed until the first time they are caught. This is a huge obstacle to researchers trying to determine motivation and risk of sexual offending. Perhaps the most valid and reliable way of uncovering this information is to first study sexual offenders who are known to have gone on to commit more sexual offenses and

then statistically determine what factors they had in common in their lives during the offending behavior. These factors become the foundation for evaluating an offender and determining his or her risk level for committing another sexual offense in the future.

Criminogenic risk factors fall into two main categories: static and dynamic. Static factors are based on historical data that indicate someone is more likely to reoffend sexually. At the foundation of static risk factors is the old adage "past behavior is the best predictor of future behavior." Therefore, static risk factors generally include elements of the individual's criminal history and victimology, as well as age. In general, all criminals tend to decrease their antisocial and criminal behavior as they age. With static risk factors, once a client receives a score and corresponding risk level, that category can never improve because it is based on historical data.

Dynamic factors allow for the tracking of progress as well as increased or decreased risk levels based on how the individual is behaving currently. Examples of dynamic risk factors include intimacy deficits, social skill deficits, impulsivity, deviant sexual interest, a lack of sexual regulation, and being uncooperative with supervision. Both static and dynamic risk factors are assessed when a sexual offender begins postincarceration treatment and then dynamic risk factors are reassessed annually to track progress and to develop further treatment planning. Sexual offenders' treatment services and monitoring services correspond to their risk levels. Low-risk offenders receive the lowest level of treatment services and monitoring, and highest risk offenders are reserved for more treatment and stricter monitoring.

SEXUAL VIOLENCE IN ADULT PRISONS AND JAILS

Starting in the late 1960s, researchers attempted to estimate the number of inmates who experienced some form of sexual assault in prison, but estimates varied tremendously. In 2001, Human Rights Watch released a report titled *No Escape: Male Rape in U.S. Prisons* portraying and detailing the dehumanizing condition of inmates who experience sexual assault while incarcerated. In the face of evidence suggesting that 13% of inmates in the United States had been sexually assaulted at some point during their incarceration, a bipartisan coalition of over 100 entities organized to pass the Prison Rape Elimination Act (PREA) that was signed into law in 2003. Utilizing the research that has derived from the PREA, this entry addresses the prevalence of sexual violence in prisons; the development of recommendations for reducing such violence, including inmate risk assessments; and the implementation of programs that seek to eliminate sexual violence in prisons.

PREA Mandates

PREA authorized the expenditure of US\$302 million over a 5-year period to provide for the analysis of the incidence and effects of prison rape in federal, state, and local correctional institutions and to provide information, resources, recommendations, and funding intended to protect individuals from prison rape. The act also created the National Prison Rape Elimination Commission (NPREC) to study prison rape and submit a set of recommendations to Congress. Failure of the NPREC to promptly develop recommendations stalled the program for several years. The U.S. Department of

Justice estimates that it will cost US\$6.9 billion between 2012 and 2026 to implement PREA or an average compliance cost per facility of US\$55,000 for prisons and US\$50,000 for jails. These numbers were examined carefully by the U.S. Department of Justice during a 3-year review process with economic experts concluding that the costs would reach a break-even point if the standards reduced the annual number of victims of prison rape by less than 1% on an annual basis.

Research

Among its many mandates, PREA required the Bureau of Justice Statistics (BJS) to collect data on the incidence and prevalence of prison rape in a nationally representative manner that included at least a 10% random sample of all federal, state, and county prison inmates. Using a rigorous methodology, since 2004, BJS has undertaken the Survey of Sexual Victimization, the National Inmate Survey, and the National Former Prisoner Survey.
